## Books In The Series

- **Risk First: The Menagerie:** Book one of the **Risk-First** series argues the case for viewing *all* of the activities on a software project through the lens of *managing risk*. It introduces the menagerie of different risks you're likely to meet on a software project, naming and classifying them so that we can try to understand them better.
- **Risk First: Tools and Practices:** Book two of the **Risk First** series explores the relationship between software project risks and the tools and practices we use to mitigate them. Due for publication in 2020.

## Online

Material for the books is freely available to read, drawn from [risk-first.org](http://risk-first.org).

# Preface

Welcome to Risk-First!

Let's cover some of the big questions up-front: The why, what, who, how and where of *The Menagerie*.

## Why

"Scrum, Waterfall, Lean, Prince2: what do they all have in common?"

I've started this because, on my career journey, I've noticed that the way I do things doesn't seem to match up with the way the books *say* it should be done. And, I found this odd and wanted to explore it further. Hopefully, you, the reader, will find something of use in this.

I started with this observation: *Development Teams* put a lot of faith in methodology. Sometimes, this faith is often so strong it borders on religion. (Which in itself is a concern.) For some, this is Prince2. For others, it might be Lean or Agile.

*Developers* put a lot of faith in *particular tools* too. Some developers are pro-or-anti-Java, others are pro-or-anti-XML. All of them have their views coloured by their *experiences* (or lack of) with these tools. Was this because their past projects *succeeded* or *failed* because of them?

As time went by, I came to see that the choice of methodology, process or tool was contingent on the problem being solved, and the person solving the problem. We don't face a shortage of tools in IT, or a shortage of methodologies, or a shortage of practices. Essentially, that all the tools and methodologies that the industry had supplied were there to help *minimize the risk of my project failing*.

This book considers that perspective: that building software is all about *managing risk*, and that these methodologies are acknowledgements of this

fact, and they differ because they have *different ideas* about which are the most important *risks to manage*.

## What This Is

Hopefully, after reading this, you'll come away with:

- An appreciation of how risk underpins everything we do as developers, whether we want it to or not.
- A framework for evaluating methodologies, tools and practices and choosing the right one for the task-at-hand.
- A recontextualization of the software process as being an exercise in mitigating different kinds of risk.
- The tools to help you decide when a methodology or tool is *letting you down*, and the vocabulary to argue for when it's a good idea to deviate from it.

This is not intended to be a rigorously scientific work: I don't believe it's possible to objectively analyze a field like software development in any meaningful, statistically significant way. (For one, things just change too fast.)

"I have this Pattern"

Does that diminish it? If you have visited the TVTropes website, you'll know that it's a set of web-pages describing *common patterns* of narrative, production, character design etc. to do with fiction. For example:

tbd.

Is it scientific? No. Is it correct? Almost certainly. TVTropes is a set of *empirical patterns* for how stories on TV and other media work. It's really useful, and a lot of fun. (Warning: it's also incredibly addictive).

In the same way, tbd, the tbd published a book called "Design Patterns: tbd". Which shows you patterns of *structure* within Object-Oriented programming:

tbd.

## **Patterns For Practitioners**

This book aimed to be a set of *useful* patterns which practitioners could use in their software to achieve certain goals. “I have this pattern” was a phrase used to describe how they had seen a certain set of constraints before, and how they had solved it in software.

This book was a set of experts handing down their battle-tested practices for other developers to use, and, whether you like patterns or not, knowing them is an important part of being a software developer, as you will see them used everywhere you go and probably use them yourself.

In the same way, this book aims to be a set of *Patterns for Software Risk*. Hopefully after reading this book, you will see where risk hides in software projects, and have a name for it when you see it.

## **Towards a “Periodic Table”**

In the latter chapters of “The Menagerie” we try to assemble these risk patterns into a cohesive whole. Projects fail because of risks, and risks arise from predictable sources.

## **What This is Not**

This is not intended to be a rigorously scientific work: I don’t believe it’s possible to objectively analyze a field like software development in any meaningful, statistically significant way. (For one, things just change too fast.)

Neither is this site isn’t going to be an exhaustive guide of every possible software development practice and methodology. That would just be too long and tedious.

Neither is this really a practitioner’s guide to using any particular methodology: If you’ve come here to learn the best way to do Retrospectives, then you’re in the wrong place. There are plenty of places you can find that information already. Where possible, this site will link to or reference concepts on Wikipedia or the wider internet for further reading on each subject.

## **Who**

This work is intended to be read by people who work on software projects, and especially those who are involved in managing software projects.

If you work collaboratively with other people in a software process, you should find Risk-First a useful lexicon of terms to help describe the risks you face.

But here's a warning: This is going to be a depressing book to read. It is book one of a two-book series, but in **Book One** you only get to meet the bad guy.

While **Book Two** is all about *how to succeed*, This book is all about how projects *fail*. In it, we're going to try and put together a framework for understanding the risk of failure, in order that we can reconstruct our understanding of our activities on a project based on avoiding it.

So, if you are interested in *avoiding your project failing*, this is probably going to be useful knowledge.

## For Developers

Risk-First is a tool you can deploy to immediately improve your ability to plan your work.

Frequently, as developers we find software methodologies “done to us” from above. Risk-First is a toolkit to help *take apart* methodologies like Scrum, Lean and Prince2, and understand them. Methodologies are *bicycles*, rather than *religions*. Rather than simply *believing*, we can take them apart and see how they work.

## For Project Managers and Team Leads

All too often, Project Managers don't have a full grasp of the technical details of their projects. And this is perfectly normal, as the specialization belongs below them. However, projects fail because risks materialize, and risks materialize because the devil is in those details.

This seems like a lost cause, but there is hope: the ways in which risks materialize on technical projects is the same every time. With Risk-First we are attempting to name each of these types of risk, which allows for a dialog with developers about which risks they face, and the order they should be tackled.

Risk-First allows a project manager to pry open the black box of development and talk with developers about their work, and how it will affect the project. It is another tool in the (limited) arsenal of techniques a project manager can bring to bear on the task of delivering a successful project.

## How

One of the original proponents of the Agile Manifesto, Kent Beck, begins his book Extreme Programming by stating:

“It’s all about risk” > Kent Beck

This is a promising start. From there, he introduces his methodology, Extreme Programming, and explains how you can adopt it in your team, the features to observe and the characteristics of success and failure. However, while *Risk* has clearly driven the conception of Extreme Programming, there is no clear model of software risk underpinning the work, and the relationship between the practices he espouses and the risks he is avoiding are hidden.

In this book, we are going to introduce a model of software project risk. This means that in **Book Two** (Risk-First: Tools and Practices), we can properly analyse Extreme Programming (and Scrum, Waterfall, Lean and all the others) and *understand* what drives them. Since they are designed to deliver successful software projects, they must be about mitigate risks, and we will uncover *exactly which risks are mitigated and how they do it*.

## Where

All of the material for this book is available Open Source on [github.com](https://github.com)<sup>1</sup>, and at the [risk-first.org](https://risk-first.org)<sup>2</sup> website. Please visit, your feedback is appreciated.

There is no compulsion to buy a print or digital version of the book, but we'd really appreciate the support. So, if you've read this and enjoyed it, how about buying a copy for someone else to read?

## A Note on References

Where possible, references are to the Wikipedia<sup>3</sup> website. Wikipedia is not perfect. There is a case for linking to the original articles and papers, but by using Wikipedia references are free and easy for everyone to access, and hopefully will exist for a long time into the future.

On to The Executive Summary

---

<sup>2</sup><https://risk-first.org>

<sup>3</sup><https://wikipedia.org>

# Executive Summary

## 1. There are Lots of Ways of Running Software Projects

There are lots of different ways to look at a project. For example, metrics such as “number of open tickets”, “story points”, “code coverage” or “release cadence” give us a numerical feel for how things are going and what needs to happen next. We also judge the health of projects by the practices used on them - Continuous Integration, Unit Testing or Pair Programming, for example.

Software methodologies, then, are collections of tools and practices: “Agile”, “Waterfall”, “Lean” or “Phased Delivery” (for example) all suggest different approaches to running a project, and are opinionated about the way they think projects should be done and the tools that should be used.

None of these is necessarily more “right” than another- they are suitable on different projects at different times.

A key question then is: **how do we select the right tools for the job?**

## 2. We can Look at Projects in Terms of Risks

One way to examine a project in-flight is by looking at the risks it faces.

Commonly, tools such as RAID logs and RAG status reporting are used. These techniques should be familiar to project managers and developers everywhere.

However, the Risk-First view is that we can go much further: that each item of work being done on the project is mitigating a particular risk. Risk isn’t something that just appears in a report, it actually drives *everything we do*.

For example:

- A story about improving the user login screen can be seen as reducing *the risk of users not signing up*.

- A task about improving the health indicators could be seen as mitigating *the risk of the application failing and no-one reacting to it*.
- Even a task as basic as implementing a new function in the application is mitigating *the risk that users are dissatisfied and go elsewhere*.

**One assertion of Risk-First therefore, is that every action you take on a project is to mitigate some risk.**

### 3. We Can Break Down Risks on a Project Methodically

Although risk is usually complicated and messy, other industries have found value in breaking down the types of risks that affect them and addressing them individually.

For example:

- In manufacturing, *tolerances* allow for calculating the likelihood of defects in production.
- In finance, reserves are commonly set aside for the risks of stock-market crashes, and teams are structured around monitoring these different risks.
- The insurance industry is founded on identifying particular risks and providing financial safety-nets for when they occur, such as death, injury, accident and so on.

Software risks are difficult to quantify, and mostly, the effort involved in doing so *exactly* would outweigh the benefit. Nevertheless, there is value in spending time building *classifications of risk for software*. That's what Risk-First does: describes the set of *risk patterns* we see every day on software projects.

With this in place, we can:

- Talk about the types of risks we face on our projects, using an appropriate language.
- Expose Hidden Risks that we hadn't considered before.
- Weigh the risks against each other, and decide which order to tackle them.

## 4. We Can Analyse Tools and Techniques in Terms of how they Mitigate Risk

If we accept the assertion above that *all* the actions we take on a project are about mitigating risks, then it stands to reason that the tools and techniques available to us on a project are there for mitigating different types of risks.

For example:

- If we do a Code Review, we are partly trying to mitigate the risks of bugs slipping through into production, and also mitigate the Key-Man Risk of knowledge not being widely-enough shared.
- If we write Unit Tests, we're also mitigating the risk of bugs going to production, but we're also mitigating against future changes breaking our existing functionality.
- If we enter into a contract with a supplier, we are mitigating the risk of the supplier vanishing and leaving us exposed. With the contract in place, we have legal recourse against this risk.

**Different tools are appropriate for mitigating different types of risks.**

## 5. Different Methodologies for Different Risk Profiles

In the same way that our tools and techniques are appropriate to dealing with different risks, the same is true of the methodologies we use on our projects. We can use a Risk-First approach to examine the different methodologies, and see which risks they address.

For example:

- **Agile** methodologies prioritise mitigating the risk that requirements capture is complicated, error-prone and that requirements change easily.
- **Waterfall** takes the view that coding effort is an expensive risk, and that we should build plans up-front to avoid it.
- **Lean** takes the view that risk lies in incomplete work and wasted work, and aims to minimize that.

Although many developers have a methodology-of-choice, the argument here is that there are tradeoffs with all of these choices. Methodologies are like *bicycles*, rather than *religions*. Rather than simply *believing*, we can take them apart and see how they work.

We can place methodologies within a framework, and show how choice of methodology is contingent on the risks faced.

## 6. Driving Development With a Risk-First Perspective

We have described a model of risk within software projects, looking something like this:

*Figure 1: Methodologies, Risks, Practices*

How do we take this further?

The first idea we explore is that of the Risk Landscape: Although the software team can't remove risk from their project, they can take actions that move them to a place in the Risk Landscape where the risks on the project are more favourable than where they started.

From there, we examine basic risk archetypes you will encounter on the software project, to build up a Taxonomy of Software Risk, and look at which specific tools you can use to mitigate each kind of risk.

Then, we look at different software practices, and how they mitigate various risks. Beyond this we examine the question: *how can a Risk-First approach inform the use of this technique?*

For example:

- If we are introducing a **Sign-Off** in our process, we have to balance the risks it *mitigates* (coordination of effort, quality control, information sharing) with the risks it *introduces* (delays and process bottlenecks).
- If we have **Redundant Systems**, this mitigates the risk of a *single point of failure*, but introduces risks around *synchronizing data* and *communication* between the systems.
- If we introduce **Process**, this may make it easier to *coordinate as a team* and *measure performance* but may lead to bureaucracy, focusing on the wrong goals or over-rigid interfaces to those processes.

Risk-First aims to provide a framework in which we can *analyse these choices* and weigh up *accepting* versus *mitigating* risks.

**Still interested? Then dive into reading the introduction.**

# **Part I**

# **Introduction**

# A Simple Scenario

First up, I'm going to introduce a simple model for thinking about risk.

## 1.1 A Simple Scenario

Lets for a moment forget about software completely, and think about *any endeavor at all* in life. It could be passing a test, mowing the lawn or going on holiday. Choose something now. I'll discuss from the point of view of "cooking a meal for some friends", but you can play along with your own example.

### Goal In Mind

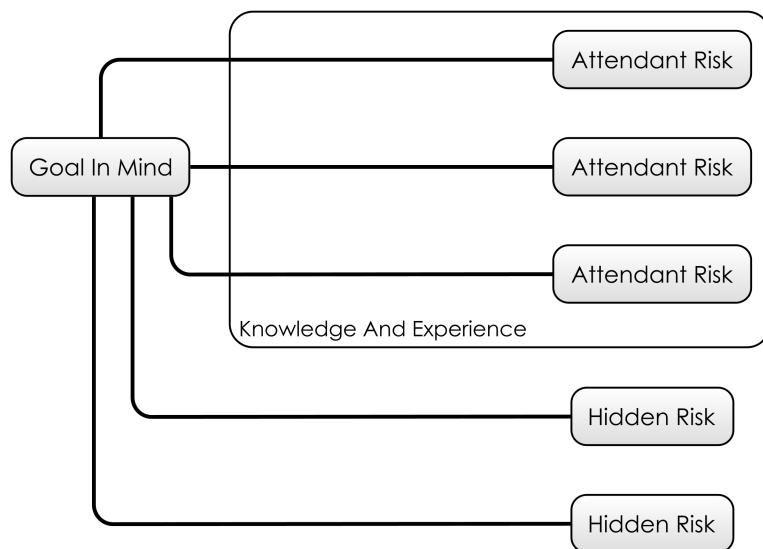

Now, in this endeavour, we want to be successful. That is to say, we have a Goal In Mind: we want our friends to go home satisfied after a decent meal, and not to feel hungry. As a bonus, we might also want to spend time talking with them before and during the meal. So, now to achieve our Goal In Mind we *probably* have to do some tasks.

If we do nothing, our friends will turn up and maybe there's nothing in the house for them to eat. Or maybe, the thing that you're going to cook is going to take hours and they'll have to sit around and wait for you to cook it and they'll leave before it's ready. Maybe you'll be some ingredients short, or maybe you're not confident of the steps to prepare the meal and you're worried about messing it all up.

### Attendant Risk

These *nagging doubts* that are going through your head I'll call the Attendant Risks: they're the ones that will occur to you as you start to think about what

will happen.

*Figure 1.1: Goal In Mind, with the risks you know about*

When we go about preparing this wonderful evening, we can with these risks and try to mitigate them: shop for the ingredients in advance, prepare parts of the meal, maybe practice the cooking in advance. Or, we can wing it, and sometimes we'll get lucky.

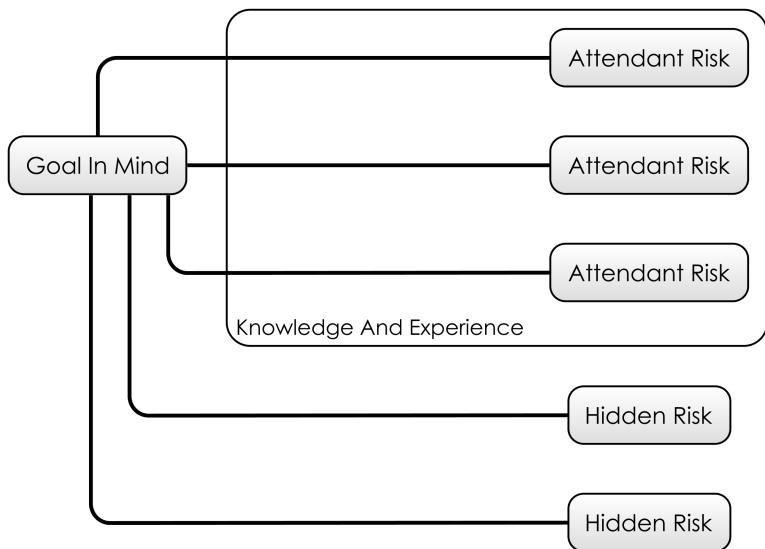

How much effort we expend on mitigating Attendant Risks depends on how great we think they are: for example, if you know it's a 24-hour shop, you'll probably not worry too much about getting the ingredients well in advance (although, the shop *could still be closed*).

## Hidden Risks

There are also hidden Attendant Risks that you might not know about: if you're poaching eggs for dinner, you might know that fresh eggs poach best. These are the "Unknown Unknowns" of Rumsfeld's model<sup>1</sup>.

Different people will evaluate the risks differently. (That is, worry about them more or less.) They'll also *know* about different risks. They might have cooked the recipe before, or organised lots more dinner parties than you.

<sup>1</sup>[https://en.wikipedia.org/wiki/There\\_are\\_known\\_unknowns](https://en.wikipedia.org/wiki/There_are_known_unknowns)

*Figure 1.2: Goal In Mind, the risks you know about and the ones you don't*

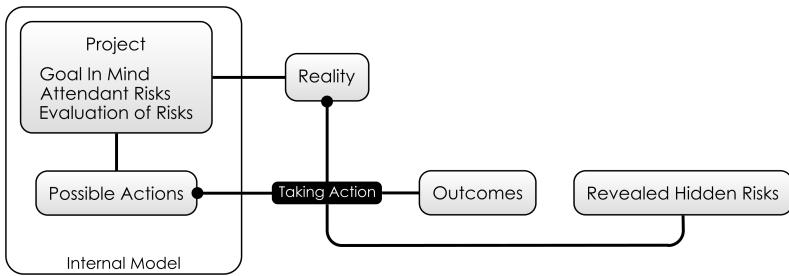

How we evaluate the risks, and which ones we know about depends on our **knowledge** and **experience**, then. And that varies from person to person (or team to team). Lets call this our Internal Model, and it's something we build on and improve with experience (of organising dinner parties, amongst everything else).

## Model Meets Reality

As the dinner party gets closer, we make our preparations, and the inadequacies of the Internal Model become apparent, and we learn what we didn't know. The Hidden Risks reveal themselves; things we were worried about may not materialise, things we thought would be minor risks turn out to be greater.

Our model is forced into contact with reality, and the model changes.

If we had a good model, and took the right actions, we should see positive outcomes. If we failed to mitigate risks, or took inappropriate actions, we'll probably see negative outcomes.

*Figure 1.3: How taking action affects Reality, and also changes your internal model*

## 1.2 On To Software

In this website, we're going to look at the risks in the software process and how these are mitigated by the various methodologies you can choose from.

Let's examine the scenario of a new software project, and expand on the simple model being outlined above: instead of a single person, we are likely to have a team, and our model will not just exist in our heads, but in the code we write.

On to Development Process

**Part II**

**Risk**

# Risk Landscape

Risk is messy. It's not always easy to tease apart the different components of risk and look at them individually. Let's look at a high-profile recent example to see why.

## 2.1 The Financial Crisis

In the Financial Services<sup>1</sup> industry, whole *departments* exist to calculate things like:

- Market Risk<sup>2</sup>: the risk that the amount some asset you hold/borrow/have loaned is going to change in value.
- Credit Risk<sup>3</sup>: the risk that someone who owes you a payment at a specific point in time might not pay it back.
- Liquidity Risk<sup>4</sup>: the risk that you can't find a market to sell/buy something, usually leading to a shortage of ready cash.

... and so on. But, we don't need to know the details exactly to understand this story.

They get expressed in ways like this:

“we have a 95% chance that today we'll lose less than č100”

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Financial\\_services](https://en.wikipedia.org/wiki/Financial_services)

<sup>2</sup>[https://en.wikipedia.org/wiki/Market\\_risk](https://en.wikipedia.org/wiki/Market_risk)

<sup>3</sup>[https://en.wikipedia.org/wiki/Credit\\_risk](https://en.wikipedia.org/wiki/Credit_risk)

<sup>4</sup>[https://en.wikipedia.org/wiki/Liquidity\\_risk](https://en.wikipedia.org/wiki/Liquidity_risk)

In the financial crisis, though, these models of risk didn't turn out to be much use. Although there are lots of conflicting explanations of what happened, one way to look at it is this:

- Liquidity difficulties (i.e. amount of cash you have for day-to-day running of the bank) caused some banks to not be able to cover their interest payments.
- This caused credit defaults (the thing that Credit Risk measures were meant to guard against) even though the banks *technically* were solvent.
- That meant that, in time, banks got bailed out, share prices crashed and there was lots of Quantitative Easing<sup>5</sup>.
- All of which had massive impacts on the markets in ways that none of the Market Risk models foresaw.

All the Risks were correlated<sup>6</sup>. That is, they were affected by the *same underlying events, or each other*.

## 2.2 The Risk Landscape Again

It's like this with software risks, too, sadly.

In Meeting Reality, we looked at the concept of the Risk Landscape, and how a software project tries to *navigate* across this landscape, testing the way as it goes, and trying to get to a position of *more favourable risk*.

It's tempting to think of our Risk Landscape as being like a Fitness Landscape<sup>7</sup>. That is, you have a "cost function" which is your height above the landscape, and you try and optimise by moving downhill in a Gradient Descent<sup>8</sup> fashion.

However, there's a problem with this: As we said in Risk Theory, we don't have a cost function. We can only guess at what risks there are. And, we have to go on our *experience*. For this reason, I prefer to think of the Risk Landscape as a terrain which contains *fauna* and *obstacles* (or, specifically Boundaries).

I am going to try and show you some of the fauna of the Risk Landscape. We know every project is different, so every Risk Landscape is also different. But, just as I can tell you that the landscape outside your window will probably will have some roads, trees, fields, forests, buildings, and that the buildings

---

<sup>5</sup>[https://en.wikipedia.org/wiki/Quantitative\\_easing](https://en.wikipedia.org/wiki/Quantitative_easing)

<sup>6</sup><https://www.investopedia.com/terms/c/correlation.asp>

<sup>7</sup>[https://en.wikipedia.org/wiki/Fitness\\_landscape](https://en.wikipedia.org/wiki/Fitness_landscape)

<sup>8</sup>[https://en.wikipedia.org/wiki/Gradient\\_descent](https://en.wikipedia.org/wiki/Gradient_descent)

are likely to be joined together by roads, I can tell you some general things about risks too.

In fact, we're going to try and categorize the kinds of things we see on this Risk Landscape. But, this isn't going to be perfect:

- One risk can "blend" into another just like sometimes a "field" is also a "car-park" or a building might contain some trees (but isn't a forest).
- There is *correlation* between different risks: one risk may cause another, or two risks may be due to the same underlying cause.
- As we saw in Part 1, mitigating one risk can give rise to another, so risks are often *inversely correlated*.

## 2.3 Why Should We Categorize The Risks?

This is a "spotters' guide" to risks, not an in-depth encyclopedia.

If we were studying insects, this might be a guide giving you a description and a picture of each insect, telling you where to find it and what it does. That doesn't mean that this is *all* there is to know. Just as a scientist could spend her entire life studying a particular species of bee, each of the risks we'll look at really has a whole sub-discipline of Computer Science attached to it, which we can't possibly hope to cover all of.

As software developers, we can't hope to know the detailed specifics of the whole discipline of Complexity Theory<sup>9</sup>, or Concurrency Theory<sup>10</sup>. But, we're still required to operate in a world where these things exist. So, we may as well get used to them, and ensure that we respect their primacy. We are operating in *their* world, so we need to know the rules.

## 2.4 We're all Naturalists Now

This is a new adventure. There's a long way to go. Just as naturalists are able to head out and find new species of insects and plants, we should expect to do the same. This is by no means a complete picture - it's barely a sketch.

It's a big, crazy, evolving world of software. Help to fill in the details. Report back what you find.

---

<sup>9</sup>[https://en.wikipedia.org/wiki/Complexity\\_theory](https://en.wikipedia.org/wiki/Complexity_theory)

<sup>10</sup>[https://en.wikipedia.org/wiki/Concurrency\\_\(computer\\_science\)](https://en.wikipedia.org/wiki/Concurrency_(computer_science))

## 2.5 Our Tour Itinerary

Below is a table outlining the different risks we'll see. There *is* an order to this: the later risks are written assuming a familiarity with the earlier ones. Hopefully, you'll stay to the end and see everything, but you're free to choose your own tour if you want to.

Risk	Description
Feature Risk	When you haven't built features the market needs, or they contain bugs, or the market changes underneath you.
Complexity Risk	Your software is so complex it makes it hard to change, understand or run.
Communication Risk	Risks associated with getting messages heard and understood.
Dependency Risk	Risks of depending on other people, products, software, functions, etc. This is a general look at dependencies, before diving into specifics like...
Schedule Risk	Risks associated with having a dependency on time (or money).
Software Dependency Risk	When you choose to depend on a software library, service or function.
Process Risk	When you depend on a business process, or human process to give you something you need.
Boundary Risk	Risks due to making decisions that limit your choices later on. Sometimes, you go the wrong way on the Risk Landscape and it's hard to get back to where you want to be.
Agency Risk	Risks that staff have their own Goals, which might not align with those of the project or team.
Coordination Risk	Risks due to the fact that systems contain multiple agents, which need to work together.
Map And Territory Risk	Risks due to the fact that people don't see the world as it really is. (After all, they're working off different, imperfect Internal Models.)

Risk	Description
Operational Risk	Software is embedded in a system containing people, buildings, machines and other services. Operational risk considers this wider picture of risk associated with running a software service or business in the real world.

On each page we'll start by looking at the category of the risk *in general*, and then break this down into some specific subtypes. At the end, in Staging and Classifying we'll have a recap about what we've seen and make some guesses about how things fit together.

So, let's get started with Feature Risk.

# Feature Risk

Feature Risk is the category of software risk to do with features that have to be in your software. It is the risk that you face by *not having features that your clients need*.

In a way, Feature Risk is very fundamental: if there were *no* feature risk, the job would be done already, either by you, or by another product, and the product would be perfect!

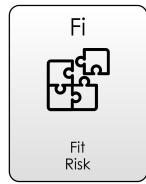

As a simple example, if your needs are served perfectly by Microsoft Excel, then you don't have any Feature Risk. However, the day you find Microsoft Excel wanting, and decide to build an Add-On is the day when you first appreciate some Feature Risk.

Not considering Feature Risk means that you might be building the wrong functionality, for the wrong audience or at the wrong time. And eventually, this will come down to lost money, business, acclaim, or whatever else reason you are doing your project for. So let's unpack this concept into some of its variations.

## 3.1 Feature Fit Risk

This is the one we've just discussed above: the feature that you (or your clients) want to use in the software *isn't there*. Now, as usual, you could call this an issue, but we're calling it a Risk because it's not clear exactly *how many* people are affected, or how badly.

- This might manifest itself as complete *absence* of something you need, e.g "Where is the word count?"
- It could be that the implementation isn't complete enough, e.g "why can't I add really long numbers in this calculator?"

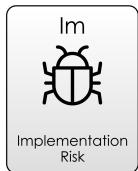

- Risk that the needs of the client don't coincide with services provided by the supplier.

*Figure 3.1: Feature Risk*

## Features Don't Work Properly

Feature Risk also includes things that don't work as expected: That is to say, bugs<sup>1</sup>. Although the distinction between "a missing feature" and "a broken feature" might be worth making in the development team, we can consider these both the same kind of risk: *the software doesn't do what the user expects*.

- Risk that the functionality you are providing doesn't match the features the client is expecting, due to poor or partial implementation.

*Figure 3.2: Implementation Risk*

(At this point, it's worth pointing out that sometimes, *the user expects the wrong thing*. This is a different but related risk, which could be down to Training or Documentation or simply Poor User Interface and we'll look at that more in Communication Risk.)

## 3.2 Regression Risk

Regression Risk is basically risk of breaking existing features in your software when you add new ones. As with the previous risks, the eventual result is the same; customers don't have the features they expect. This can become a problem as your code-base gains Complexity, as it becomes impossible to keep a complete Internal Model of the whole thing.

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Software\\_bug](https://en.wikipedia.org/wiki/Software_bug)

- Risk that the functionality you provide changes for the worse, over time.

*Figure 3.3: Regression Risk*

Also, while delivering new features can delight your customers, breaking existing ones will annoy them. This is something we'll come back to in Reputation Risk.

### 3.3 Conceptual Integrity Risk

- Risk that the software you provide is too complex, or doesn't match the expectations of your clients' internal models.

*Figure 3.4: Conceptual Integrity Risk*

Sometimes, users *swear blind* that they need some feature or other, but it runs at odds with the design of the system, and plain *doesn't make sense*. Often, the development team can spot this kind of conceptual failure as soon as it enters the Backlog. Usually, it's in coding that this becomes apparent.

tbd: feature phones.

Sometimes, it can go for a lot longer. I once worked on some software that was built as a score-board within a chat application. However, after we'd added much-asked-for commenting and reply features to our score-board, we realised we'd implemented a chat application *within a chat application*, and had wasted our time enormously.

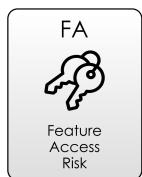

Which leads to Greenspun's 10th Rule:

“Any sufficiently complicated C or Fortran program contains an ad-hoc, informally-specified, bug-ridden, slow implementation of half of Common Lisp.” - Greenspun’s 10th Rule, *Wikipedia*<sup>2</sup>

This is a particularly pernicious kind of Feature Risk which can only be mitigated by good Design. Human needs are fractal in nature: the more you examine them, the more differences you can find. The aim of a product is to capture some needs at a *general* level: you can’t hope to “please all of the people all of the time”.

Conceptual Integrity Risk is the risk that chasing after features leaves the product making no sense, and therefore pleasing no-one.

### 3.4 Feature Access Risk

- Risks due to some clients not having access to some or all of the features in your product.

*Figure 3.5: Feature Access Risk*

Sometimes, features can work for some people and not others: this could be down to Accessibility<sup>3</sup> issues, language barriers or localization.

You could argue that the choice of *platform* is also going to limit access: writing code for XBox-only leaves PlayStation owners out in the cold. This is largely Feature Access Risk, though Dependency Risk is related here.

In Marketing, minimizing Feature Access Risk is all about Segmentation: trying to work out *who* your product appeals to, and tailoring it to that particular market, but for technologists, increasing Feature Access means increasing complexity: you have to deliver the software on more platforms, localized in more languages, with different configurations of features at different price-points. Mitigating Feature Access Risk therefore means increased effort and complexity (which we’ll come to later).

<sup>2</sup>[https://en.wikipedia.org/wiki/Greenspun%27s\\_tenth\\_rule](https://en.wikipedia.org/wiki/Greenspun%27s_tenth_rule)

<sup>3</sup><https://en.wikipedia.org/wiki/Accessibility>

## Market Risk

Feature Access Risk is related, of course, to Market Risk, which I introduced on the Risk Landscape page as being the value that the market places on a particular asset. Since the product you are building is your asset, it makes sense that you'll face Market Risk on it:

- Risk that the value your clients place on the features you supply will change, over time.

*Figure 3.6: Market Risk*

"Market risk is the risk of losses in positions arising from movements in market prices." - Market Risk, *Wikipedia*

I face market risk when I own (i.e. have a *position* in) some Apple<sup>4</sup> stock. Apple's stock price will decline if a competitor brings out an amazing product, or if fashions change and people don't want their products any more.

In the same way, *you* have Market Risk on the product or service you are building: the *market* decides what it is prepared to pay for this, and it tends to be outside your control.

## 3.5 Feature Drift Risk

**Feature Drift** is the tendency that the features people need *change over time*. For example, at one point in time, supporting IE6 was right up there for website developers, but it's not really relevant anymore. Although that change took *many* years to materialize, other changes are more rapid.

The point is: Requirements captured *today* might not make it to *tomorrow*, especially in the fast-paced world of IT. This is partly because the market *evolves* and becomes more discerning. This happens in several ways:

---

<sup>4</sup><http://apple.com>

- Risk that the features required by clients will change and evolve over time.

*Figure 3.7: Feature Drift Risk*

- Features present in competitor's versions of the software become *the baseline*, and they're expected to be available in your version.
- Certain ways of interacting become the norm (e.g. query keyboards, or the control layout in cars: these don't change with time).
- Features decline in usefulness: *Printing* is less important now than it was, for example.

Feature Drift Risk is *not the same thing* as **Requirements Drift**, which is the tendency projects have to expand in scope as they go along. There are lots of reasons they do that, a key one being the Hidden Risks uncovered on the project as it progresses.

## Fashion

Fashion plays a big part in IT, as this infographic on website design shows<sup>5</sup>. True, websites have got easier to use as time has gone by, and users now expect this. Also, bandwidth is greater now, which means we can afford more media and code on the client side. However, *fashion* has a part to play in this.

By being *fashionable*, websites are communicating: *this is a new thing, this is relevant, this is not terrible*: all of which is mitigating a Communication Risk. Users are all-too-aware that the Internet is awash with terrible, abandoned sites that are going to waste their time. How can you communicate that you're not one of them to your users?

## 3.6 Delight

If this breakdown of Feature Risk seems reductive, then try not to think of it that way: the aim *of course* should be to delight users, and turn them into

---

<sup>5</sup><https://designers.hubspot.com/blog/the-history-of-web-design-infographic>

fans. That's a laudable Goal, but should be treated in the usual Risk-First way: *pick the biggest risk you can mitigate next.*

Consider Feature Risk from both the down-side and the up-side:

- What are we missing?
- How can we be *even better*?

Hopefully, this has given you some ideas about what Feature Risk involves. Hopefully, you might be able to identify a few more specific varieties. But, it's time to move on and look in more detail at Complexity Risk and how it affects what we build.

## 3.7 Analysis

At this point, it would be easy to stop and say, look, here are a bunch of Feature Risk issues that you could face. But, it turns out that we're going to be relying heavily on Feature Risk as we go on in order to build our understanding of other risks, so it's probably worth spending a bit of time up front to classify what we've found.

The Feature Risks identified here basically exist in a 3-dimensional space:

- **Fit:** How well the features fit for a particular client.
- **Audience:** The range of clients (the *market*) that may be able to use this feature.
- **Evolution:** The way the fit and the audience changes and evolves as time goes by.

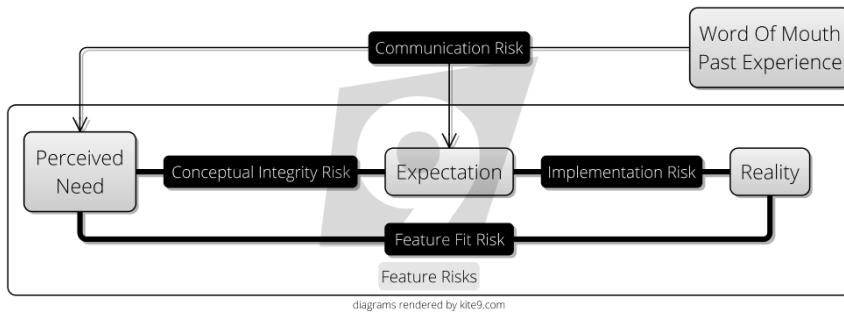

### Fit

“Survival Of The Fittest” - Darwin, tbd.

Darwin's conception of fitness was not one of athletic prowess, but how well an organism worked within the landscape.

tbd: definition of biological fitness

Fit Risk, Conceptual Integrity Risk and Implementation Risk all hint at different aspects of this “fitness”. We can conceive of the relationships between them in the following way:

**Figure 3.8: Feature Risks Assembled**

For further reading, you can check out The Service Quality Model<sup>6</sup>, which this model is derived from. This model analyses the types of *quality gaps* in services, and how consumer expectations and perceptions of a service arise. In Staging And Classifying, we'll come back and build on this model further.

## Fit and Audience

Two risks, Feature Access Risk and Market Risk consider *Fit* for a whole *Audience* of users. They are different: just as it's possible to have a small audience, but a large revenue, it's possible to have a product which has low Feature Access Risk (i.e lots of users can access it without difficulty) but high Market Risk (i.e. the market is highly volatile or capricious in its demands). *Online services* often suffer from this Market Risk rollercoaster, being one moment highly valued and the next irrelevant.

## Fit, Audience and Evolution

Two risks further consider how the **Fit** and **Audience** *change*: Regression Risk and Feature Drift Risk. We call this *evolution* in the sense that:

- Our product's features *evolve* with time, and changes made by the development team.
- Our audience changes and evolves as it is exposed to our product and competing products.
- The world as a whole is an evolving system within which our product exists.

tbd. regression risk and feature drift risk.

---

<sup>6</sup><http://en.wikipedia.org/SERVQUAL>

### 3.8 Applying Feature Risk

Consider Feature Risk carefully next time you are grooming the backlog:

- Can you judge which tasks mitigate the most Feature Risk?
- Are you delivering features that are valuable to a large audience? How well do you understand your audience? How does the size of the audience for a task impact its importance in the backlog?
- Does the audience *know* that the features exist? How do you communicate feature availability to them?
- How does writing a specification mitigate Fit Risk? For what other reasons are you writing specifications?

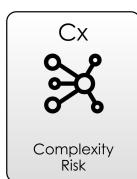

In the next chapter, we are going to unpack this third point further. Somewhere between “what the customer wants” and “what you give them” is a *dialog*. In using a software product, users are engaging in a *dialog* with its features. If the features don’t exist, hopefully they will engage in a dialog with the development team to get them added.

These dialogs are prone to risk, and this is the subject of the next chapter, Communication-Risk.

# Complexity Risk

Complexity Risk are the risks to your project due to its underlying “complexity”. Over the next few chapters, we’ll break down exactly what we mean by complexity, looking at Dependency Risk and Boundary Risk as two particular sub-types of Complexity Risk. However, in this chapter, we’re going to be specifically focusing on *code you write*: the size of your code-base, the number of modules, the interconnectedness of the modules and how well-factored the code is.

- Risks caused by the weight of complexity in the systems we create, and their resistance to change and comprehension.

*Figure 4.1: Complexity Risks*

You could think of this chapter, then, as **Codebase Risk**: We’ll look at three separate measures of codebase complexity and talk about Technical Debt, and look at places in which **Codebase Risk** is at its greatest.

## 4.1 Kolmogorov Complexity

The standard Computer-Science definition of complexity, is Kolmogorov Complexity<sup>1</sup>. This is:

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Kolmogorov\\_complexity](https://en.wikipedia.org/wiki/Kolmogorov_complexity)

“... is the length of the shortest computer program (in a pre-determined programming language) that produces the object as output.” - Kolmogorov Complexity, Wikipedia

This is a fairly handy definition for us, as it means that to in writing software to solve a problem, there is a lower bound on the size of the software we write. In practice, this is pretty much impossible to quantify. But that doesn't really matter: the techniques for *moving in that direction* are all that we are interested in, and this basically amounts to compression.

Let's say we wanted to write a javascript program to output this string:

```
abcdabcdabcdabcdabcdabcdabcdabcdabcd
```

We might choose this representation:

```
function out() {  
    return "abcdabcdabcdabcdabcdabcdabcdabcd"  
}
```

The numbers in brackets indicate how many symbols each line contains, so in total, this code block contains **53 symbols**, if you count `function`, `out` and `return` as one symbol each.

But, if we write it like this:

```
const ABCD="ABCD";  
  
function out() {  
    return ABCD+ABCD+ABCD+ABCD+ABCD+ABCD+  
          ABCD+ABCD+ABCD;  
}
```

With this version, we now have **41 symbols** (`ABCD` is a single symbol, because we could have called it anything). And with this version:

```
const ABCD="ABCD";  
  
function out() {  
    return ABCD.repeat(10)  
}
```

... we have **26 symbols**.

## Abstraction

What's happening here is that we're *exploiting a pattern*: we noticed that ABCD occurs several times, so we defined it a single time and then used it over and over, like a stamp. Separating the *definition* of something from the *use* of something as we've done here is called "abstraction". We're going to come across it over and over again in this part of the book, and not just in terms of computer programs.

By applying techniques such as Abstraction, we can improve in the direction of the Kolmogorov limit. And, by allowing ourselves to say that *symbols* (like `out` and `ABCD`) are worth one complexity point, we've allowed that we can be descriptive in our function name and `const`. Naming things is an important part of abstraction, because to use something, you have to be able to refer to it.

## Trade-Off

But we could go further down into Code Golf<sup>2</sup> territory. This javascript program plays FizzBuzz<sup>3</sup> up to 100, but is less readable than you might hope:

```
for(i=0;i<100;)document.write(((++i%3?'Fizz':(i%5?'Buzz'):i)+"<br>"))
```

(62)

So there is at some point a trade-off to be made between Complexity Risk and Communication Risk. This is a topic we'll address more in that chapter. But for now, it should be said that Communication Risk is about *misunderstanding*: The more complex a piece of software is, the more difficulty users will have understanding it, and the more difficulty developers will have changing it.

## 4.2 Connectivity

A second, useful measure of complexity comes from graph theory, and that is the connectivity of a graph:

"... the minimum number of elements (nodes or edges) that need to be removed to disconnect the remaining nodes from each other" - Connectivity, *Wikipedia*<sup>4</sup>

---

<sup>2</sup>[https://en.wikipedia.org/wiki/Code\\_golf](https://en.wikipedia.org/wiki/Code_golf)

<sup>3</sup>[https://en.wikipedia.org/wiki/Fizz\\_buzz](https://en.wikipedia.org/wiki/Fizz_buzz)

<sup>4</sup>[https://en.wikipedia.org/wiki/Connectivity\\_\(graph\\_theory\)](https://en.wikipedia.org/wiki/Connectivity_(graph_theory))

To see this in action, have a look at the below graph:

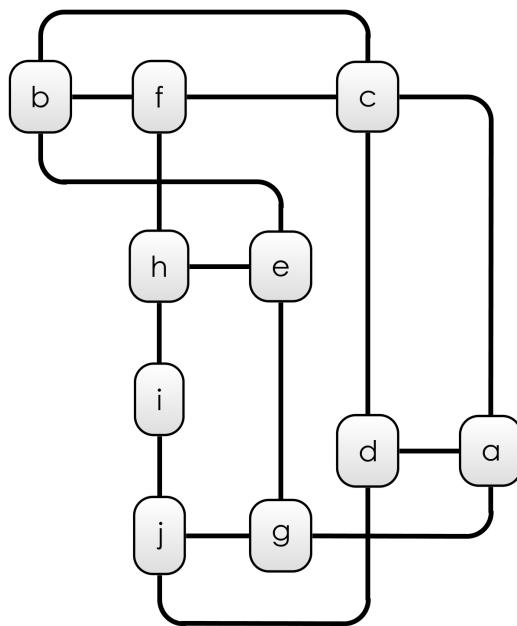

Figure 4.2: Graph 1

It has 10 vertices, labelled **a** to **j**, and it has 15 edges (or links) connecting the vertices together. If any single edge were removed from this diagram, the 10 vertices would still be linked together. Because of this, we can say that the graph is *2-connected*. That is, to disconnect any single vertex, you'd have to remove *at least* two edges.

As a slight aside, let's consider the **Kolmogorov Complexity** of this graph, by inventing a mini-language to describe graphs. It could look something like this:

```
<item> : [<item>,]* <item>      # Indicates that the item
# before the colon
# has a connection to all
# the items after the colon
```

So our graph could be defined like this:

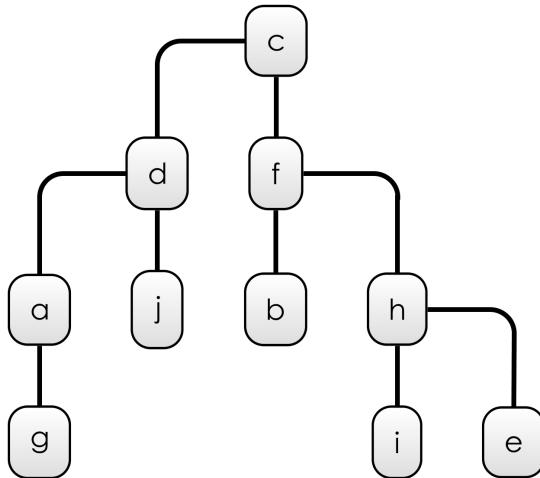

```

a: b,c,d
b: c,f,e
c: f,d
d: j
e: h,j
f: h
g: j
h: i
i: j

```

(39)

Let's remove some of those extra links:

*Figure 4.3: Graph 2*

In this graph, I've removed 6 of the edges. Now, we're in a situation where if any single edge is removed, the graph becomes *unconnected*. That is, it's broken into distinct chunks. So, it's *1-connected*.

The second graph is clearly simpler than the first. And, we can show this by looking at the **Kolgomorov Complexity** in our little language:

```

a: d,g
b: f

```

```
c: d, f  
d: j  
f: h  
e: h  
h: i
```

(25)

**Connectivity** is also **Complexity**. Heavily connected programs/graphs are much harder to work with than less-connected ones. Even *laying out* the first graph sensibly is a harder task than the second (the second is a doddle). But the reason programs with greater connectivity are harder to work with is that changing one module potentially impacts many others.

### 4.3 Hierarchies and Modularization

In the second, simplified graph, I've arranged it as a hierarchy, which I can do now that it's only 1-connected. For 10 vertices, we need 9 edges to connect everything up. It's always:

```
edges = vertices - 1
```

Note that I could pick any hierarchy here: I don't have to start at **c** (although it has the nice property that it has two roughly even sub-trees attached to it).

How does this help us? Imagine if **a - j** were modules of a software system, and the edges of the graph showed communications between the different sub-systems. In the first graph, we're in a worse position: who's in charge? What deals with what? Can I isolate a component and change it safely? What happens if one component disappears? But, in the second graph, it's easier to reason about, because of the reduced number of connections and the new hierarchy of organisation.

On the downside, perhaps our messages have farther to go now: in the original **i** could send a message straight to **j**, but now we have to go all the way via **c**. But this is the basis of Modularization<sup>5</sup> and Hierarchy<sup>6</sup>.

As a tool to battle complexity, we don't just see this in software, but everywhere in our lives. Society, business, nature and even our bodies:

---

<sup>5</sup>[https://en.wikipedia.org/wiki/Modular\\_programming](https://en.wikipedia.org/wiki/Modular_programming)

<sup>6</sup><https://en.wikipedia.org/wiki/Hierarchy>

- **Organelles** - such as Mitochondria<sup>7</sup>.
- **Cells** - such as blood cells, nerve cells, skin cells in the Human Body<sup>8</sup>.
- **Organs** - like hearts livers, brains etc.
- **Organisms** - like you and me.

The great complexity-reducing mechanism of modularization is that *you only have to consider your local environment*. Elements of the program that are “far away” in the hierarchy can be relied on not to affect you. This is somewhat akin to the **Principal Of Locality**:

“Spatial locality refers to the use of data elements within relatively close storage locations.” - Locality Of Reference, *Wikipedia*<sup>9</sup>

## 4.4 Cyclomatic Complexity

A variation on this graph connectivity metric is our third measure of complexity, Cyclomatic Complexity<sup>10</sup>. This is:

$$\text{Cyclomatic Complexity} = \text{edges} - \text{vertices} + 2P,$$

Where **P** is the number of **Connected Components** (i.e. distinct parts of the graph that aren’t connected to one another by any edges).

So, our first graph had a **Cyclomatic Complexity** of 7. ( $15 - 10 + 2$ ), while our second was 1. ( $9 - 10 + 2$ ).

Cyclomatic complexity is all about the number of different routes through the program. The more branches a program has, the greater it’s cyclomatic complexity. Hence, this is a useful metric in Testing and Code Coverage: the more branches you have, the more tests you’ll need to exercise them all.

## 4.5 More Abstraction

Although we ended up with our second graph having a **Cyclomatic Complexity** of 1 (the minimum), we can go further through abstraction, because this representation isn’t minimal from a **Kolmogorov Complexity** point-of-view. For example, we might observe that there are further similarities in the graph that we can “draw out”:

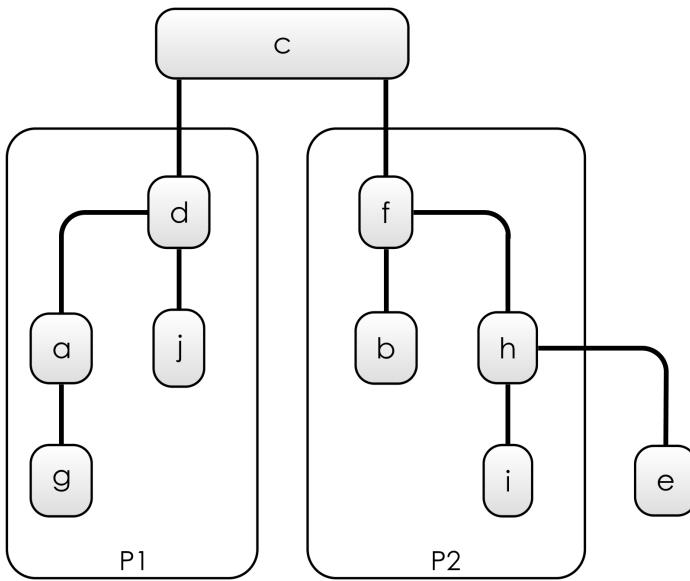

---

<sup>7</sup><https://en.wikipedia.org/wiki/Mitochondrion>

<sup>8</sup>[https://en.wikipedia.org/wiki/List\\_of\\_distinct\\_cell\\_types\\_in\\_the\\_adult\\_human\\_body](https://en.wikipedia.org/wiki/List_of_distinct_cell_types_in_the_adult_human_body)

<sup>9</sup>[https://en.wikipedia.org/wiki/Locality\\_of\\_reference](https://en.wikipedia.org/wiki/Locality_of_reference)

<sup>10</sup>[https://en.wikipedia.org/wiki/Cyclomatic\\_complexity](https://en.wikipedia.org/wiki/Cyclomatic_complexity)

*Figure 4.4: Complexity 3*

Here, we've spotted that the structure of subgraphs **P1** and **P2** are the same: we can have the same functions there to assemble those. Noticing and exploiting patterns of repetition is one of the fundamental tools we have in the fight against Complexity Risk.

So, we've looked at some measures of software structure complexity, in order that we can say "this is more complex than this". However, we've not really said why complexity entails Risk. So let's address that now by looking at two analogies, Mass and Technical Debt.

## 4.6 Complexity As Mass

The first way to look at complexity is as **Mass** or **Inertia**: a software project with more complexity has greater **Inertia** or **Mass** than one with less complexity.

Newton's Second Law states:

" $F = ma$ , ( Force = Mass x Acceleration )" - Netwon's Laws Of

Motion, Wikipedia<sup>11</sup>

That is, in order to move your project *somewhere new*, and make it do new things, you need to give it a push, and the more **Mass** it has, the more **Force** you'll need to move (accelerate) it.

**Inertia** and **Mass** are equivalent concepts in physics:

"mass is the quantitative or numerical measure of a body's inertia, that is of its resistance to being accelerated". - Inertia, Wikipedia<sup>12</sup>

You could stop here and say that the more lines of code a project contains, the higher it's mass. And, that makes sense, because in order to get it to do something new, you're likely to need to change more lines.

But there is actually some underlying sense in which *this is real*, as discussed in this Veritasium<sup>13</sup> video. To paraphrase:

"Most of your mass you owe due to E=mc<sup>2</sup>, you owe to the fact that your mass is packed with energy, because of the **interactions** between these quarks and gluon fluctuations in the gluon field... what we think of as ordinarily empty space... that turns out to be the thing that gives us most of our mass." - Your Mass is NOT From the Higgs Boson, Veritasium<sup>14</sup>

I'm not an expert in physics, *at all*, and so there is every chance that I am pushing this analogy too hard. But, substituting quarks and gluons for pieces of software we can (in a very handwaving-y way) say that more complex software has more **interactions** going on, and therefore has more mass than simple software.

The reason I am labouring this analogy is to try and make the point that Complexity Risk is really fundamental:

- Feature Risk: like **money**.
- Schedule Risk: like **time**.
- Complexity Risk: like **mass**.

---

<sup>11</sup>[https://en.wikipedia.org/wiki/Newton%27s\\_laws\\_of\\_motion](https://en.wikipedia.org/wiki/Newton%27s_laws_of_motion)

<sup>12</sup>[https://en.wikipedia.org/wiki/Inertia#Mass\\_and\\_inertia](https://en.wikipedia.org/wiki/Inertia#Mass_and_inertia)

<sup>13</sup><https://www.youtube.com/user/1veritasium>

<sup>14</sup>[https://www.youtube.com/watch?annotation\\_id=annotation\\_3771848421&feature=iv&src\\_vid=Xo232kyTs00&v=Ztc6QPNuqls](https://www.youtube.com/watch?annotation_id=annotation_3771848421&feature=iv&src_vid=Xo232kyTs00&v=Ztc6QPNuqls)

At a basic level, Complexity Risk heavily impacts on Schedule Risk: more complexity means you need more force to get things done, which takes longer.

## 4.7 Technical Debt

The most common way we talk about unnecessary complexity in software is as Technical Debt:

“Shipping first time code is like going into debt. A little debt speeds development so long as it is paid back promptly with a rewrite... The danger occurs when the debt is not repaid. Every minute spent on not-quite-right code counts as interest on that debt. Entire engineering organizations can be brought to a standstill under the debt load of an unconsolidated implementation, object-oriented or otherwise.” – Ward Cunningham, 1992<sup>15</sup>

Building a perfect first-time solution is a waste, because perfection takes a long time. You’re taking on more attendant Schedule Risk than necessary and Meeting Reality more slowly than you could.

A quick-and-dirty, over-complex implementation mitigates the same Feature Risk and allows you to Meet Reality faster (see Prototyping).

But, having mitigated the Feature Risk, you are now carrying more Complexity Risk than you necessarily need, and it’s time to think about how to Refactor the software to reduce this risk again.

## 4.8 Kitchen Analogy

It’s often hard to make the case for minimizing Technical Debt: it often feels that there are more important priorities, especially when technical debt can be “swept under the carpet” and forgotten about until later. (See Discounting The Future.)

One helpful analogy I have found is to imagine your code-base is a kitchen. After preparing a meal (i.e. delivering the first implementation), *you need to tidy up the kitchen*. This is just something everyone does as a matter of *basic sanitation*.

Now of course, you could carry on with the messy kitchen. When tomorrow comes and you need to make another meal, you find yourself needing to

---

<sup>15</sup>[https://en.wikipedia.org/wiki/Technical\\_debt](https://en.wikipedia.org/wiki/Technical_debt)

wash up saucepans as you go, or working around the mess by using different surfaces to chop on.

It's not long before someone comes down with food poisoning.

We wouldn't tolerate this behaviour in a restaurant kitchen, so why put up with it in a software project?

## 4.9 Feature Creep

In Brooks' essay "No Silver Bullet - Essence and Accident in Software Engineering", a distinction is made between:

- **Essence:** *the difficulties inherent in the nature of the software.*
  - **Accident:** *those difficulties that attend its production but are not inherent.*
- Fred Brooks, *No Silver Bullet*<sup>16</sup>

The problem with this definition is that we are accepting features of our software as *essential*.

The **Risk-First** approach is that if you want to mitigate some Feature Risk then you have to pick up Complexity Risk as a result. But, that's a *choice you get to make*.

Therefore, Feature Creep<sup>17</sup> (or Gold Plating<sup>18</sup>) is a failure to observe this basic equation: instead of considering this trade off, you're building every feature possible. This has an impact on Complexity Risk, which in turn impacts Communication Risk and also Schedule Risk.

Sometimes, feature-creep happens because either managers feel they need to keep their staff busy, or the staff decide on their own that they need to keep themselves busy. But now, we can see that basically this boils down to bad risk management.

"Perfection is Achieved Not When There Is Nothing More to Add, But When There Is Nothing Left to Take Away" - Antoine de Saint-Exupéry

- The risk that a particular approach to a change will fail.  
Caused by the fact that at some level, our internal  
models are not a complete reflection of reality.

*Figure 4.5: Dead-End Risk*

## 4.10 Dead-End Risk

Dead-End Risk is where you build functionality that you *think* is useful, only to find out later that actually, it was a dead-end, and is superceded by something else.

For example, let's say that the Accounting sub-system needed password protection (so you built this). Then the team realised that you needed a way to *change the password* (so you built that). Then, that you needed to have more than one user of the Accounting system so they would all need passwords (ok, fine).

Finally, the team realises that actually logging-in would be something that all the sub-systems would need, and that it had already been implemented more thoroughly by the Approvals sub-system.

At this point, you realise you're in a **Dead End**:

- **Option 1:** You carry on making minor incremental improvements to the accounting password system (carrying the extra Complexity Risk of the duplicated functionality).
- **Option 2:** You rip out the accounting password system, and merge in the Approvals system, surfacing new, hidden Complexity Risk in the process, due to the difficulty in migrating users from the old to new way of working.
- **Option 3:** You start again, trying to take into account both sets of requirements at the same time, again, possibly surfacing new hidden Complexity Risk due to the combined approach.

---

<sup>16</sup>[https://en.wikipedia.org/wiki/No\\_Silver\\_Bullet](https://en.wikipedia.org/wiki/No_Silver_Bullet)

<sup>17</sup>[https://en.wikipedia.org/wiki/Feature\\_creep](https://en.wikipedia.org/wiki/Feature_creep)

<sup>18</sup>[https://en.wikipedia.org/wiki/Gold\\_plating\\_\(software\\_engineering\)](https://en.wikipedia.org/wiki/Gold_plating_(software_engineering))

Sometimes, the path from your starting point to your goal on the Risk Landscape will take you to dead ends: places where the only way towards your destination is to lose something, and do it again another way.

This is because you surface new Hidden Risk along the way. And the source of a lot of this hidden risk will be unexpected Complexity Risk in the solutions you choose. This happens a lot.

## Source Control

Version Control Systems<sup>19</sup> like Git<sup>20</sup> are a useful mitigation of Dead-End Risk, because it means you can *go back* to the point where you made the bad decision and go a different way. Additionally, they provide you with backups against the often inadvertent Dead-End Risk of someone wiping the hard-disk.

## The Re-Write

**Option 3**, Rewriting code or a whole project can seem like a way to mitigate Complexity Risk, but it usually doesn't work out too well. As Joel Spolsky says:

There's a subtle reason that programmers always want to throw away the code and start over. The reason is that they think the old code is a mess. And here is the interesting observation: they are probably wrong. The reason that they think the old code is a mess is because of a cardinal, fundamental law of programming:  
*It's harder to read code than to write it.* - Things You Should Never Do, Part 1, *Joel Spolsky*<sup>21</sup>

The problem that Joel is outlining here is that the developer mistakes hard-to-understand code for unnecessary Complexity Risk. Also, perhaps there is Agency Risk because the developer is doing something that is more useful to him than the project. We're going to return to this problem in again Communication Risk.

---

<sup>19</sup>[https://en.wikipedia.org/wiki/Version\\_control](https://en.wikipedia.org/wiki/Version_control)

<sup>20</sup><https://en.wikipedia.org/wiki/Git>

<sup>21</sup><https://www.joelonsoftware.com/2000/04/06/things-you-should-never-do-part-i/>

## 4.11 Where Complexity Hides

Complexity isn't spread evenly within a software project. Some problems, some areas, have more than their fair share of issues. We're going to cover a few of these now, but be warned, this is not a complete list by any means:

- Memory Management
- Protocols / Types
- Algorithmic (Space and Time) Complexity
- Concurrency / Mutability
- Networks / Security

### Memory Management

Memory Management is another place where Complexity Risk hides:

"Memory leaks are a common error in programming, especially when using languages that have no built in automatic garbage collection, such as C and C++." - Memory Leak, Wikipedia<sup>22</sup>

Garbage Collectors<sup>23</sup> (as found in Javascript or Java) offer you the deal that they will mitigate the Complexity Risk of you having to manage your own memory, but in return perhaps give you fewer guarantees about the *performance* of your software. Again, there are times when you can't accommodate this Operational Risk, but these are rare and usually only affect a small portion of an entire software-system.

### Protocols And Types

Whenever two components of a software system need to interact, they have to establish a protocol for doing so. There are lots of different ways this can work, but the simplest example I can think of is where some component **a** calls some function **b**. e.g:

```
function b(a, b, c) {  
    return "whatever" // do something here.  
}  
  
function a() {
```

<sup>22</sup>[https://en.wikipedia.org/wiki/Memory\\_leak](https://en.wikipedia.org/wiki/Memory_leak)

<sup>23</sup>[https://en.wikipedia.org/wiki/Garbage\\_collection\\_\(computer\\_science\)](https://en.wikipedia.org/wiki/Garbage_collection_(computer_science))

```

var bOut = b("one", "two", "three");
return "something "+bOut;
}

```

If component **b** then changes in some backwards-incompatible way, say:

```

function b(a, b, c, d /* new parameter */ {
    return "whatever" // do something here.
}

```

Then, we can say that the protocol has changed. This problem is so common, so endemic to computing that we've had compilers that check function arguments since the 1960's<sup>24</sup>. The point being is that it's totally possible for the compiler to warn you about when a protocol within the program has changed.

The same is basically true of Data Types<sup>25</sup>: whenever we change the **Data Type**, we need to correct the usages of that type. Note above, I've given the javascript example, but I'm going to switch to typescript now:

```

interface BInput {
    a: string,
    b: string,
    c: string,
    d: string
}

function b(in: BInput): string {
    return "whatever" // do something here.
}

```

Now, of course, there is a tradeoff: we *mitigate* Complexity Risk, because we define the protocols / types *once only* in the program, and ensure that usages all match the specification. But the tradeoff is (as we can see in the typescript code) more *finger-typing*, which some people argue counts as Schedule Risk.

---

<sup>24</sup><https://en.wikipedia.org/wiki/Compiler>

<sup>25</sup>[https://en.wikipedia.org/wiki/Data\\_type](https://en.wikipedia.org/wiki/Data_type)

Nevertheless, compilers and type-checking are so prevalent in software that clearly, you have to accept that in most cases, the trade-off has been worth it: Even languages like Clojure<sup>26</sup> have been retro-fitted with type checkers<sup>27</sup>.

We're going to head into much more detail on this in the chapter on Protocol Risk.

## Space and Time Complexity

So far, we've looked at a couple of definitions of complexity in terms of the codebase itself. However, in Computer Science there is a whole branch of complexity theory devoted to how the software *runs*, namely Big O Complexity<sup>28</sup>.

Once running, an algorithm or data structure will consume space or run-time dependent on its characteristics. As with Garbage Collectors), these characteristics can introduce Performance Risk which can easily catch out the unwary. By and large, using off-the-shelf data structures and algorithms helps, but you still need to know their performance characteristics.

The Big O Cheatsheet<sup>29</sup> is a wonderful resource to investigate this further.

## Concurrency / Mutability

Although modern languages include plenty of concurrency primitives, (such as the `java.util.concurrent`<sup>30</sup> libraries), concurrency is *still* hard to get right.

Race conditions<sup>31</sup> and Deadlocks<sup>32</sup> *thrive* in over-complicated concurrency designs: complexity issues are magnified by concurrency concerns, and are also hard to test and debug.

Recently, languages such as Clojure have introduced persistent collections<sup>33</sup> to alleviate concurrency issues. The basic premise is that any time you want to *change* the contents of a collection, you get given back a *new collection*. So, any collection instance is immutable once created. The tradeoff is again attendant Performance Risk to mitigate Complexity Risk.

An important lesson here is that choice of language can reduce complexity: and we'll come back to this in Software Dependency Risk.

<sup>26</sup><https://clojure.org>

<sup>27</sup><https://github.com/clojure/core.typed/wiki/User-Guide>

<sup>28</sup>[https://en.wikipedia.org/wiki/Big\\_O\\_notation](https://en.wikipedia.org/wiki/Big_O_notation)

<sup>29</sup><http://bigocheatsheet.com>

<sup>30</sup><https://docs.oracle.com/javase/9/docs/api/java/util/concurrent/package-summary.html>

<sup>31</sup>[https://en.wikipedia.org/wiki/Race\\_condition](https://en.wikipedia.org/wiki/Race_condition)

<sup>32</sup><https://en.wikipedia.org/wiki/Deadlock>

<sup>33</sup>[https://en.wikipedia.org/wiki/Persistent\\_data\\_structure](https://en.wikipedia.org/wiki/Persistent_data_structure)

## **Networking / Security**

The last area I want to touch on here is networking. There are plenty of Complexity Risk perils in *anything* to do with networked code, chief amongst them being error handling and (again) protocol evolution.

In the case of security considerations, exploits *thrive* on the complexity of your code, and the weaknesses that occur because of it. In particular, Schneier's Law says, never implement your own crypto scheme:

"Anyone, from the most clueless amateur to the best cryptographer, can create an algorithm that he himself can't break. It's not even hard. What is hard is creating an algorithm that no one else can break, even after years of analysis." - Bruce Schneier, 1998<sup>34</sup>

Luckily, most good languages include crypto libraries that you can include to mitigate these Complexity Risks from your own code-base.

This is a strong argument for the use of libraries. But, when should you use a library and when should you implement yourself? This is again covered in the chapter on Software Dependency Risk.

tbd - next chapter.

costs associated with complexity risk

CHANGE is also more risky why?

---

<sup>34</sup>[https://en.wikipedia.org/wiki/Bruce\\_Schneier#Cryptography](https://en.wikipedia.org/wiki/Bruce_Schneier#Cryptography)

# Communication Risk

Communication Risk is the risk of communication between entities *going wrong*, due to loss or misunderstanding. Consider this: if we all had identical knowledge, there would be no need to do any communicating at all, and therefore and also no Communication Risk.

But, people are not all-knowing oracles. We rely on our *senses* to improve our Internal Models of the world. There is Communication Risk here - we might overlook something vital (like an oncoming truck) or mistake something someone says (like “Don’t cut the green wire”).

Communication Risk isn’t just for people; it affects computer systems too.

## 5.1 A Model Of Communication

In 1948, Claude Shannon proposed this definition of communication:

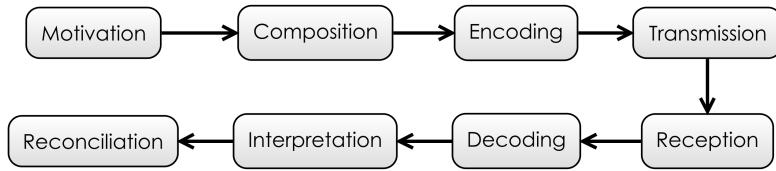

“The fundamental problem of communication is that of reproducing at one point, either exactly or approximately, a message selected at another point.” - A Mathematical Theory Of Communication, *Claude Shannon*<sup>1</sup>

And from this same paper, we get the following (slightly adapted) model.

We move from top-left (“I want to send a message to someone”) to bottom left, clockwise, where we hope the message has been understood and believed. (I’ve added this last box to Shannon’s original diagram.)

---

<sup>1</sup>[https://en.wikipedia.org/wiki/A\\_Mathematical\\_Theory\\_of\\_Communication](https://en.wikipedia.org/wiki/A_Mathematical_Theory_of_Communication)

*Figure 5.1: Shannon's Communication Model*

One of the chief concerns in Shannon's paper is the step between **Transmission** and **Reception**. He creates a theory of information (measured in **bits**), the upper-bounds of information that can be communicated over a channel and ways in which Communication Risk between these processes can be mitigated by clever **Encoding** and **Decoding** steps.

But it's not just transmission. Communication Risk exists at each of these steps. Let's imagine a short exchange where someone, **Alice** is trying to send a message to **Bob**:

- **Alice** might be **motivated** to send a message to tell **Bob** something, only to find out that *he already knew it*, or it wasn't useful information for them.
- In the **composition** stage, **Alice** might mess up the *intent* of the message: instead of "Please buy chips" she might say, "Please buy chops".
- In the **encoding** stage, **Alice** might not speak clearly enough to be understood, and...
- In the **transmission** stage, **Alice** might not say it loudly enough for **Bob** to...
- **receive** the message clearly (maybe there is background noise).
- Having heard **Alice** say something, can **Bob** **decode** what was said into a meaningful sentence?
- Then, assuming that, will they **interpret** correctly which type of chips (or chops) **Alice** was talking about? Does "Please buy chips" convey all the information they need?
- Finally, assuming *everything else*, will **Bob** believe the message? Will they **reconcile** the information into their Internal Model and act on it? Perhaps not, if **Bob** thinks that there are chips at home already.

## 5.2 Approach To Communication Risk

There is a symmetry about the steps going on in Shannon's diagram, and we're going to exploit this in order to break down Communication Risk into its main types.

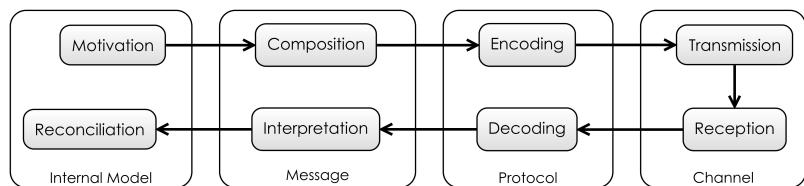

Figure 5.2: Communication Risk 2

To get inside Communication Risk, we need to understand **Communication** itself, whether between *machines, people or products*: we'll look at each in turn. In order to do that, we're going to examine four basic concepts in each of these settings:

- Channels<sup>2</sup>, the medium via which the communication is happening.
- Protocols<sup>3</sup> - the systems of rules that allow two or more entities of a communications system to transmit information.
- Messages<sup>4</sup>: The information we want to convey.
- Internal Models: the sources and destinations for the messages. Updating internal models (whether in our heads or machines) is the reason why we're communicating.

And, as we look at these four areas, we'll consider the Attendant Risks of each.

## 5.3 Channels

There are lots of different types of media for communicating (e.g. TV, Radio, DVD, Talking, Posters, Books, Phones, The Internet, etc. ) and they all have different characteristics. When we communicate via a given medium, it's called a *channel*.

<sup>2</sup>[https://en.wikipedia.org/wiki/Communication\\_channel](https://en.wikipedia.org/wiki/Communication_channel)

<sup>3</sup>[https://en.wikipedia.org/wiki/Communication\\_protocol](https://en.wikipedia.org/wiki/Communication_protocol)

<sup>4</sup><https://en.wikipedia.org/wiki/Message>

The channel *characteristics* depend on the medium, then. Some obvious ones are cost, utilisation, number of people reached, simplex or duplex (parties can transmit and receive at the same time), persistence (a play vs a book, say), latency (how long messages take to arrive) and bandwidth (the amount of information that can be transmitted in a period of time).

Channel characteristics are important: in a high-bandwidth, low-latency situation, **Alice** and **Bob** can *check* with each other that the meaning was transferred correctly. They can discuss what to buy, they can agree that **Alice** wasn't lying or playing a joke.

The channel characteristics also imply suitability for certain *kinds* of messages. A documentary might be a great way of explaining some economic concept, whereas an opera might not be.

## 5.4 Channel Risk

Shannon discusses that no channel is perfect: there is always the **risk of noise** corrupting the signal. A key outcome from Shannon's paper is that there is a tradeoff: within the capacity of the channel (the **Bandwidth**), you can either send lots of information with *higher* risk that it is wrong, or less information with *lower* risk of errors. And, rather like the Kolgomorov complexity result, the more *randomness* in the signal, the less compressible it is, and therefore the more *bits* it will take to transmit.

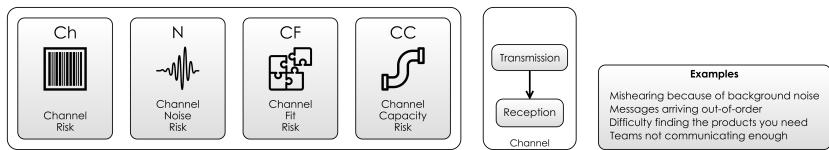

- Risks due to the inadequacy of the physical channel used to communicate our messages. e.g. noise, loss, interception, corruption.

*Figure 5.3: Communication Channel Risk*

But channel risk goes wider than just this mathematical example: messages might be delayed or delivered in the wrong order, or not be acknowledged when they do arrive. Sometimes, a channel is just an inappropriate way of communicating. When you work in a different time-zone to someone else on your team, there is *automatic* Channel Risk, because instantaneous communication is only available for a few hours' a day.

When channels are **poor-quality**, less communication occurs. People will try to communicate just the most important information. But, it's often impossible to know a-priori what constitutes "important". This is why Extreme Programming recommends the practice of Pair Programming and siting all the developers together: although you don't know whether useful communication will happen, you are mitigating Channel Risk by ensuring high-quality communication channels are in place.

At other times, channels can contain so much information that we can't hope to receive all the messages. In these cases, we don't even observe the whole channel, just parts of it. For example, you might have a few YouTube channels that you subscribe to, but hundreds of hours of video are being posted on YouTube every second, so there is no way you can keep up with all of it.

*Figure 5.4: Communication Channels*

## Marketing Communications

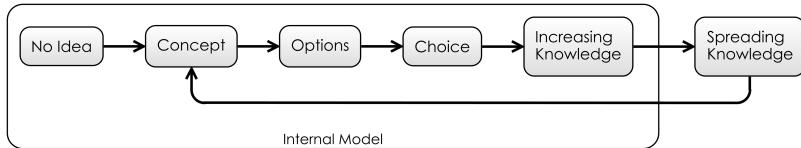

When we are talking about a product or a brand, mitigating Channel Risk is the domain of Marketing Communications<sup>5</sup>. How do you ensure that the information about your (useful) project makes it to the right people? How do you address the right channels?

This works both ways. Let's look at some of the **Channel Risks** from the point of view of a hypothetical software tool, **D**, which would really useful in my software:

- The concept that there is such a thing as **D** which solves my problem isn't something I'd even considered.
- I'd like to use something like **D**, but how do I find it?
- There are multiple implementations of **D**, which is the best one for the task?
- I know **D**, but I can't figure out how to solve my problem in it.
- I've chosen **D**, I now need to persuade my team that **D** is the correct solution...

<sup>5</sup>[https://en.wikipedia.org/wiki/Marketing\\_communications](https://en.wikipedia.org/wiki/Marketing_communications)

- ... and then they also need to understand **D** to do their job too.

*Figure 5.5: Communication Marketing*

Internal Models don't magically get populated with the information they need: they fill up gradually, as shown in this diagram. Popular products and ideas *spread*, by word-of-mouth or other means. Part of the job of being a good technologist is to keep track of new **Ideas**, **Concepts** and **Options**, so as to use them as Dependencies when needed.

## 5.5 Protocols

In this chapter, I want to examine the concept of Communication Protocols and how they relate to Abstraction.

So, to do this, let's look in a bit of detail at how web pages are loaded. When considering this, we need to broaden our terminology. Although so far we've talked about **Senders** and **Receivers**, we now need to talk from the point of view of who-depends-on-who. If you're *depended on*, then you're a "Server", whereas if you require communication with something else, you're a "Client". Thus, clients depend on servers in order to load pages.

This is going to involve (at least) six separate protocols, the top-most one being the HTTP Protocol<sup>6</sup>. As far as the HTTP Protocol is concerned, a *client* makes an **HTTP Request** at a specific URL and the **HTTP Response** is returned in a predictable format that the browser can understand.

Let's have a quick look at how that works with a `curl` command, which allows me to load a web page from the command line. We're going to try and load Google's preferences page, and see what happens. If I type:

```
> curl -v http://google.com/preferences
```

---

<sup>6</sup>[https://en.wikipedia.org/wiki/Hypertext\\_Transfer\\_Protocol](https://en.wikipedia.org/wiki/Hypertext_Transfer_Protocol)

## 1. DNS - Domain Name System

Then, the first thing that happens is this:

```
* Rebuilt URL to: http://google.com/  
*   Trying 216.58.204.78...
```

At this point, curl has used DNS<sup>7</sup> to *resolve* the address “google.com” to an IP address. This is some Abstraction: instead of using the machine’s IP Address<sup>8</sup> on the network, 216.58.204.78, I can use a human-readable address, google.com. The address google.com doesn’t necessarily resolve to that same address each time: *They have multiple IP addresses for google.com.* But, for the rest of the curl request, I’m now set to just use this one.

## 2. IP - Internet Protocol

But this hints at what is beneath the abstraction: although I’m loading a web-page, the communication to the Google server happens by IP Protocol<sup>9</sup> - it’s a bunch of discrete “packets” (streams of binary digits). You can think of a packet as being like a real-world parcel or letter.

Each packet consists of two things:

- An address, which tells the network components (such as routers and gateways) where to send the packet, much like you’d write the address on the outside of a parcel.
- The *payload*, the stream of bytes for processing at the destination. Like the contents of the parcel.

But, even this concept of “packets” is an Abstraction. Although all the components of the network interoperate with this protocol, we might be using Wired Ethernet, or WiFi, 4G or *something else*.

## 3. 802.11 - WiFi Protocol

I ran this at home, using WiFi, which uses IEEE 802.11 Protocol<sup>10</sup>, which allows my laptop to communicate with the router wirelessly, again using an agreed, standard protocol. But even *this* isn’t the bottom, because this is

---

<sup>7</sup>[https://en.wikipedia.org/wiki/Domain\\_Name\\_System](https://en.wikipedia.org/wiki/Domain_Name_System)

<sup>8</sup>[https://en.wikipedia.org/wiki/IP\\_address](https://en.wikipedia.org/wiki/IP_address)

<sup>9</sup>[https://en.wikipedia.org/wiki/Internet\\_Protocol](https://en.wikipedia.org/wiki/Internet_Protocol)

<sup>10</sup>[https://en.wikipedia.org/wiki/IEEE\\_802.11](https://en.wikipedia.org/wiki/IEEE_802.11)

actually probably specifying something like MIMO-OFDM<sup>11</sup>, giving specifications about frequencies of microwave radiation, antennas, multiplexing, error-correction codes and so on. And WiFi is just the first hop: after the WiFi receiver, there will be protocols for delivering the packets via the telephony system.

## 4. TCP - Transmission Control Protocol

Anyway, the next thing that happens is this:

```
* TCP_NODELAY set
* Connected to google.com (216.58.204.78) port 80 (#0)
```

The second obvious Abstraction going on here is that curl now believes it has a TCP<sup>12</sup> connection. The TCP connection abstraction gives us the surety that the packets get delivered in the right order, and retried if they go missing. Effectively it *guarantees* these things, or that it will have a connection failure if it can't keep its guarantee.

But, this is a fiction - TCP is built on the IP protocol, packets of data on the network. So there are lots of packets floating around which say "this connection is still alive" and "I'm message 5 in the sequence" and so on in order to maintain this fiction. But that means that the HTTP protocol can forget about this complexity and work with the fiction of a connection.

## 5. HTTP - Hypertext Transfer Protocol

Next, we see this:

```
> GET /preferences HTTP/1.1      (1)
> Host: google.com              (2)
> User-Agent: curl/7.54.0        (3)
> Accept: */*                   (4)
>                                (5)
```

This is now the HTTP protocol proper, and these 5 lines are sending information *over the connection* to the Google server.

- (1) says what version of HTTP we are using, and the path we're loading (/preferences in this case).

---

<sup>11</sup><https://en.wikipedia.org/wiki/MIMO-OFDM>

<sup>12</sup>[https://en.wikipedia.org/wiki/Transmission\\_Control\\_Protocol](https://en.wikipedia.org/wiki/Transmission_Control_Protocol)

- (2) to (4) are *headers*. They are name-value pairs, separated with a colon. The HTTP protocol specifies a bunch of these names, and later versions of the protocol might introduce newer ones.
- (5) is an empty line, which indicates that we're done with the headers, please give us the response. And it does:

```

< HTTP/1.1 301 Moved Permanently
< Location: http://www.google.com/preferences
< Content-Type: text/html; charset=UTF-8
< Date: Sun, 08 Apr 2018 10:24:34 GMT
< Expires: Tue, 08 May 2018 10:24:34 GMT
< Cache-Control: public, max-age=2592000
< Server: gws
< Content-Length: 230
< X-XSS-Protection: 1; mode=block
< X-Frame-Options: SAMEORIGIN
<
<HTML><HEAD><meta http-equiv="content-type"
content="text/html; charset=utf-8">
<TITLE>301 Moved</TITLE></HEAD><BODY>
<H1>301 Moved</H1>
The document has moved
</BODY></HTML>
* Connection #0 to host google.com left intact

```

There's a lot going on here, but we can break it down really easily into 3 chunks:

1. The first line is the HTTP Status Code<sup>13</sup>. 301 is a code meaning that the page has moved.
2. The next 9 lines are HTTP headers again (name-value pairs). The `Location:` directive tells us where the page has moved to. Instead of trying `http://google.com/preferences`, we should have used:

`http://www.google.com/preferences.`

3. The lines starting `<HTML>` are now some HTML to display on the screen to tell the user that the page has moved.

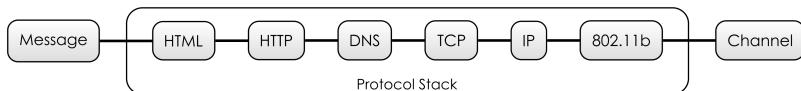

---

<sup>13</sup>[https://en.wikipedia.org/wiki/List\\_of\\_HTTP\\_status\\_codes](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes)

## 6. HTML - Hypertext Markup Language

Although HTML<sup>14</sup> is a language, a language is also a protocol. (After all, language is what we use to encode our ideas for transmission as speech.) In the example we gave, this was a very simple page telling the client that it's looking in the wrong place. In most browsers, you don't get to see this: the browser will understand the meaning of the 301 error and redirect you to the location.

Let's look at all the protocols we saw here:

*Figure 5.6: Protocol Stack*

Each protocol “passes on” to the next one in the chain. On the left, we have the representation most suitable for the *messages*: HTTP is designed for browsers to use to ask for and receive web pages. As we move right, we are converting the message more and more into a form suitable for the Channel: in this case, microwave transmission.

By having a stack of protocols, we are able to apply Separation Of Concerns<sup>15</sup>, each protocol handling just a few concerns:

- HTML Abstraction: A language for describing the contents of a web-page.
- HTTP Abstraction: Name-Value pairs, agreed on by both curl and Google, URLs and error codes.
- DNS Abstraction: Names of servers to IP Addresses.
- TCP Abstraction: The concept of a “connection” with guarantees about ordering and delivery.
- IP Abstraction: “Packets” with addresses and payloads.
- WiFi Abstraction: “Networks”, 802.11 flavours.
- Transmitters, Antennas, error correction codes, etc.

HTTP “stands on the shoulders of giants”. Not only does it get to use pre-existing protocols like TCP and DNS to make it's life easier, it got 802.11 “for free” when this came along and plugged into the existing IP protocol. This is

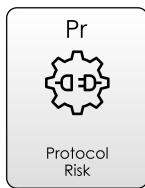

<sup>14</sup><https://en.wikipedia.org/wiki/HTML>

<sup>15</sup>[https://en.wikipedia.org/wiki/Separation\\_of\\_concerns](https://en.wikipedia.org/wiki/Separation_of_concerns)

the key value of abstraction: you get to piggy-back on *existing* patterns, and use them yourself.

The protocol mediates between the message and the channel. Where this goes wrong, we have Protocol Risk. This is a really common issue for IT systems, but also sometimes for human communication too.

## 5.6 Protocol Risk

- Risks due to the failure of encoding or decoding messages between two parties in communication.

*Figure 5.7: Protocol Risk*

Generally, any time where you have different parts of a system communicating with each other, and one part can change incompatibly with another you have Protocol Risk.

Locally, (within our own project), where we have control, we can mitigate this risk using compile-time checking (as discussed already in Complexity Risk), which essentially forces all clients and servers to agree on protocol. But, the wider the group that you are communicating with, the less control you have and the more chance there is of Protocol Risk.

Let's look at some types of Protocol Risk:

### Protocol Incompatibility Risk

The people you find it *easiest* to communicate with are your friends and family, those closest to you. That's because you're all familiar with the same protocols. Someone from a foreign country, speaking a different language and having a different culture, will essentially have a completely incompatible protocol for spoken communication to you.

Within software, there are also competing, incompatible protocols for the same things, which is maddening when your protocol isn't supported. Although the world seems to be standardizing, there used to be *hundreds* of

different image formats. Photographs often use TIFF<sup>16</sup>, RAW<sup>17</sup> or JPEG<sup>18</sup>, whilst we also have SVG<sup>19</sup> for vector graphics, GIF<sup>20</sup> for images and animations and PNG<sup>21</sup> for other bitmap graphics.

## Protocol Versioning Risk

Even when systems are talking the same protocol, there can be problems. When we have multiple, different systems owned by different parties, on their own upgrade cycles, we have **Protocol Versioning Risk**: the risk that either client or server could start talking in a version of the protocol that the other side hasn't learnt yet. There are various mitigating strategies for this. We'll look at two now: **Backwards Compatibility** and **Forwards Compatibility**.

## Protocol Complexity

tbd. abstraction - virtue between two vices. Postel's law.

### Backward Compatibility

Backwards Compatibility mitigates Protocol Versioning Risk. Quite simply, this means, supporting the old format until it falls out of use. If a server is pushing for a change in protocol it either must ensure that it is Backwards Compatible with the clients it is communicating with, or make sure they are upgraded concurrently. When building web services<sup>22</sup>, for example, it's common practice to version all APIs so that you can manage the migration. Something like this:

- Server publishes /api/v1/something.
- Clients use /api/v1/something.
- Server publishes /api/v2/something.
- Clients start using /api/v2/something.
- Clients (eventually) stop using /api/v2/something.
- Server retires /api/v2/something API.

---

<sup>16</sup><https://en.wikipedia.org/wiki/TIFF>

<sup>17</sup>[https://en.wikipedia.org/wiki/Raw\\_image\\_format](https://en.wikipedia.org/wiki/Raw_image_format)

<sup>18</sup><https://en.wikipedia.org/wiki/JPEG>

<sup>19</sup>[https://en.wikipedia.org/wiki/Scalable\\_Vector\\_Graphics](https://en.wikipedia.org/wiki/Scalable_Vector_Graphics)

<sup>20</sup><https://en.wikipedia.org/wiki/GIF>

<sup>21</sup>[https://en.wikipedia.org/wiki/Portable\\_Network\\_Graphics](https://en.wikipedia.org/wiki/Portable_Network_Graphics)

<sup>22</sup>[https://en.wikipedia.org/wiki/Web\\_service](https://en.wikipedia.org/wiki/Web_service)

## Forward Compatibility

HTML and HTTP provide “graceful failure” to mitigate Protocol Risk: while it’s expected that all clients can parse the syntax of HTML and HTTP, it’s not necessary for them to be able to handle all of the tags, attributes and rules they see. The specification for both these standards is that if you don’t understand something, ignore it. Designing with this in mind means that old clients can always at least cope with new features, but it’s not always possible.

JavaScript *can’t* support this: because the meaning of the next instruction will often depend on the result of the previous one.

Does human language support this? To some extent! New words are added to our languages all the time. When we come across a new word, we can either ignore it, guess the meaning, ask or look it up. In this way, human language has **Forward Compatibility** features built in.

## Protocol Implementation Risk

A second aspect of Protocol Risk exists in heterogeneous computing environments, where protocols have been independently implemented based on standards. For example, there are now so many different browsers, all supporting different levels of HTTP, HTML and JavaScript that it becomes impossible to test comprehensively over all the different versions. To mitigate as much Protocol Risk as possible, generally we run tests in a subset of browsers, and use a lowest-common-denominator approach to choosing protocol and language features.

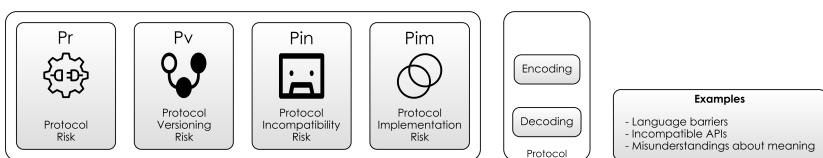

Figure 5.8: Communication Protocols Risks

## 5.7 Messages

Although Shannon’s Communication Theory is about transmitting **Messages**, messages are really encoded **Ideas** and **Concepts**, from an **Internal Model**.

- Risks caused by the difficulty of composing and interpreting messages in the communication process.

*Figure 5.9: Message Risk*

## Internal Model Assumption Risk

When we construct messages in a conversation, we have to make judgements about what the other person already knows. When talking to children, it's often hard work because they *assume* that you have knowledge of everything they do. This is called Theory Of Mind<sup>23</sup>: the appreciation that your knowledge is different to other people's, and adjusting your messages accordingly.

When teaching, this is called The Curse Of Knowledge<sup>24</sup>: teachers have difficulty understanding students' problems *because they already understand the subject*. For example, if I want to tell you about a new JDBC Driver<sup>25</sup>, this pre-assumes that you know what JDBC is: the message has a dependency on prior knowledge.

## Message Dependency Risk

A second, related problem is actually Dependency Risk, which is covered more thoroughly in the next chapter. Often, messages assume that you have followed everything up to that point already, otherwise again, your Internal Model will not be rich enough to understand the new messages.

This happens when messages get missed, or delivered out of order. In the past, TV shows were only aired once a week at a particular time. So writers were constrained plot-wise by not knowing whether their audience would have seen the previous week's episode. Therefore, often the state of the show would "reset" week-to-week, allowing you to watch it in *any* order.

The same **Message Dependency Risk** exists for computer software: if there is replication going on between instances of an application, and one of the instances misses some messages, you end up with a "Split Brain"<sup>26</sup> scenario,

<sup>23</sup>[https://en.wikipedia.org/wiki/Theory\\_of\\_mind](https://en.wikipedia.org/wiki/Theory_of_mind)

<sup>24</sup>[https://en.wikipedia.org/wiki/Curse\\_of\\_knowledge](https://en.wikipedia.org/wiki/Curse_of_knowledge)

<sup>25</sup>[https://en.wikipedia.org/wiki/JDBC\\_driver](https://en.wikipedia.org/wiki/JDBC_driver)

<sup>26</sup>[https://en.wikipedia.org/wiki/Split-brain\\_\(computing\)](https://en.wikipedia.org/wiki/Split-brain_(computing))

where later messages can't be processed because they refer to an application state that doesn't exist. For example, a message saying:

```
Update user 53's surname to 'Jones'
```

only makes sense if the application has previously had the message

```
Create user 53 with surname 'Smith'
```

## Misinterpretation Risk

People don't rely on rigorous implementations of abstractions like computers do; we make do with fuzzy definitions of concepts and ideas. We rely on Abstraction to move between the name of a thing and the *idea of a thing*.

While machines only process *information*, people's brains run on concepts and ideas. For people, abstraction is critical: nothing exists unless we have a name for it. Our world is just atoms, but we don't think like this. *The name is the thing*.

"The famous pipe. How people reproached me for it! And yet, could you stuff my pipe? No, it's just a representation, is it not? So if I had written on my picture "This is a pipe", I'd have been lying!" - Rene Magritte, of *The Treachery of Images*<sup>27</sup>

This brings about Misinterpretation Risk: names are not *precise*, and concepts mean different things to different people. We can't be sure that people have the same meaning for concepts that we have.

## Invisibility Risk

Another cost of Abstraction is Invisibility Risk. While abstraction is a massively powerful technique, (as we saw above in the chapter on Protocols, it allows things like the Internet to happen) it lets the function of a thing hide behind the layers of abstraction and become invisible.

---

<sup>27</sup>[https://en.wikipedia.org/wiki/The\\_Treachery\\_of\\_Images](https://en.wikipedia.org/wiki/The_Treachery_of_Images)

## Invisibility Risk In Software

As soon as you create a function, you are doing abstraction. You are saying: "I now have this operation. The details, I won't mention again, but from now on, it's called *f*" And suddenly, "*f*" hides. It is working invisibly. Things go on in *f* that people don't necessarily need to understand. There may be some documentation, or tacit knowledge around what *f* is, and what it does, but it's not necessarily right. Referring to *f* is a much simpler job than understanding *f*.

We try to mitigate this via (for the most part) documentation, but this is a terrible deal: because we can't understand the original, (un-abstracted) implementation, we now need to write some simpler documentation, which *explains* the abstraction, in terms of further abstractions, and this is where things start to get murky.

Invisibility Risk is mainly Hidden Risk. (Mostly, *you don't know what you don't know*.) But you can carelessly *hide things from yourself* with software:

- Adding a thread to an application that doesn't report whether it's worked, failed, or is running out of control and consuming all the cycles of the CPU.
- Redundancy can increase reliability, but only if you know when servers fail, and fix them quickly. Otherwise, you only see problems when the last server fails.
- When building a webservice, can you assume that it's working for the users in the way you want it to?

When you build a software service, or even implement a thread, ask yourself: "How will I know next week that this is working properly?" If the answer involves manual work and investigation, then your implementation has just cost you in Invisibility Risk.

## Invisibility Risk In Conversation

Invisibility Risk is risk due to information not sent. But because humans don't need a complete understanding of a concept to use it, we can cope with some Invisibility Risk in communication, and this saves us time when we're talking. It would be *painful* to have conversations if, say, the other person needed to understand everything about how cars worked in order to discuss cars.

For people, Abstraction is a tool that we can use to refer to other concepts, without necessarily knowing how the concepts work. This divorcing of

“what” from “how” is the essence of abstraction and is what makes language useful.

The debt of Invisibility Risk comes due when you realise that *not* being given the details *prevents* you from reasoning about it effectively. Let’s think about this in the context of a project status meeting, for example:

- Can you be sure that the status update contains all the details you need to know?
- Is the person giving the update wrong or lying?
- Do you know enough about the details of what’s being discussed in order to make informed decisions about how the project is going?

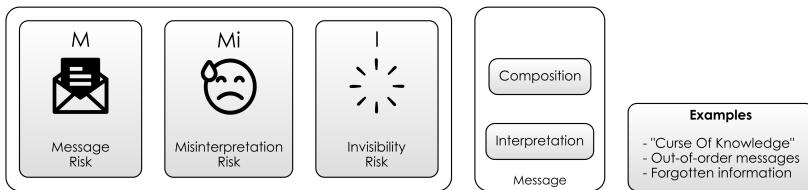

Figure 5.10: Message Risk

## 5.8 Internal Models

So finally, we are coming to the root of the problem: communication is about transferring ideas and concepts from one Internal Model to another.

The communication process so far has been fraught with risks, but we have a few more to come.

### Trust & Belief Risk

Although protocols can sometimes handle security features of communication (such as Authentication<sup>28</sup> and preventing man-in-the-middle attacks<sup>29</sup>), trust goes further than this, intersecting with Agency Risk: can you be sure that the other party in the communication is acting in your best interests?

Even if the receiver trusts the communicator, they may not trust the message. Let’s look at some reasons for that:

<sup>28</sup><https://en.wikipedia.org/wiki/Authentication>

<sup>29</sup>[https://en.wikipedia.org/wiki/Man-in-the-middle\\_attack](https://en.wikipedia.org/wiki/Man-in-the-middle_attack)

- Weltanschauung (World View)<sup>30</sup>: The ethics, values and beliefs in the receiver's Internal Model may be incompatible to those from the sender.
- Relativism<sup>31</sup> is the concept that there are no universal truths. Every truth is from a frame of reference. For example, what constitutes *offensive language* is dependent on the listener.
- Psycholinguistics<sup>32</sup> is the study of humans acquire languages. There are different languages and dialects, (and *industry dialects*), and we all understand language in different ways, take different meanings and apply different contexts to the messages.

From the point-of-view of Marketing Communications choosing the right message is part of the battle. You are trying to communicate your idea in such a way as to mitigate Belief Risk and Trust Risk.

## Reputational Risk

tbd.

## Learning-Curve Risk

If the messages we are receiving force us to update our Internal Model too much, we can suffer from the problem of "too steep a Learning Curve<sup>33</sup>" or "Information Overload<sup>34</sup>", where the messages force us to adapt our Internal Model too quickly for our brains to keep up.

Commonly, the easiest option is just to ignore the information channel completely in these cases.

## Reading Code

It's often been said that code is *harder to read than to write*:

"If you ask a software developer what they spend their time doing, they'll tell you that they spend most of their time writing code. However, if you actually observe what software developers spend their time doing, you'll find that they spend most of their time trying to understand code." - When Understanding Means Rewriting, *Coding Horror*<sup>35</sup>

---

<sup>30</sup>[https://en.wikipedia.org/wiki/World\\_view](https://en.wikipedia.org/wiki/World_view)

<sup>31</sup><https://en.wikipedia.org/wiki/Relativism>

<sup>32</sup><https://en.wikipedia.org/wiki/Psycholinguistics>

<sup>33</sup>[https://en.wikipedia.org/wiki/Learning\\_curve](https://en.wikipedia.org/wiki/Learning_curve)

<sup>34</sup>[https://en.wikipedia.org/wiki/Information\\_overload](https://en.wikipedia.org/wiki/Information_overload)

<sup>35</sup><https://blog.codinghorror.com/when-understanding-means-rewriting/>

By now it should be clear that it's going to be *both* quite hard to read and write: the protocol of code is actually designed for the purpose of machines communicating, not primarily for people to understand. Making code human readable is a secondary concern to making it machine readable.

But now we should be able to see the reasons it's harder to read than write too:

- When reading code, you are having to shift your Internal Model to wherever the code is, accepting decisions that you might not agree with and accepting counter-intuitive logical leaps. i.e. Learning Curve Risk. (*cf. Principle of Least Surprise*<sup>36</sup>)
- There is no Feedback Loop between your Internal Model and the Reality of the code, opening you up to Misinterpretation Risk. When you write code, your compiler and tests give you this.
- While reading code *takes less time* than writing it, this also means the Learning Curve is steeper.

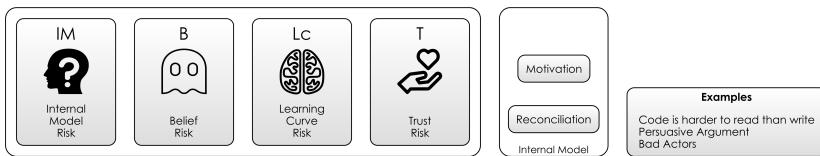

Figure 5.11: Internal Model Risks

## 5.9 Communication Risk Wrap Up

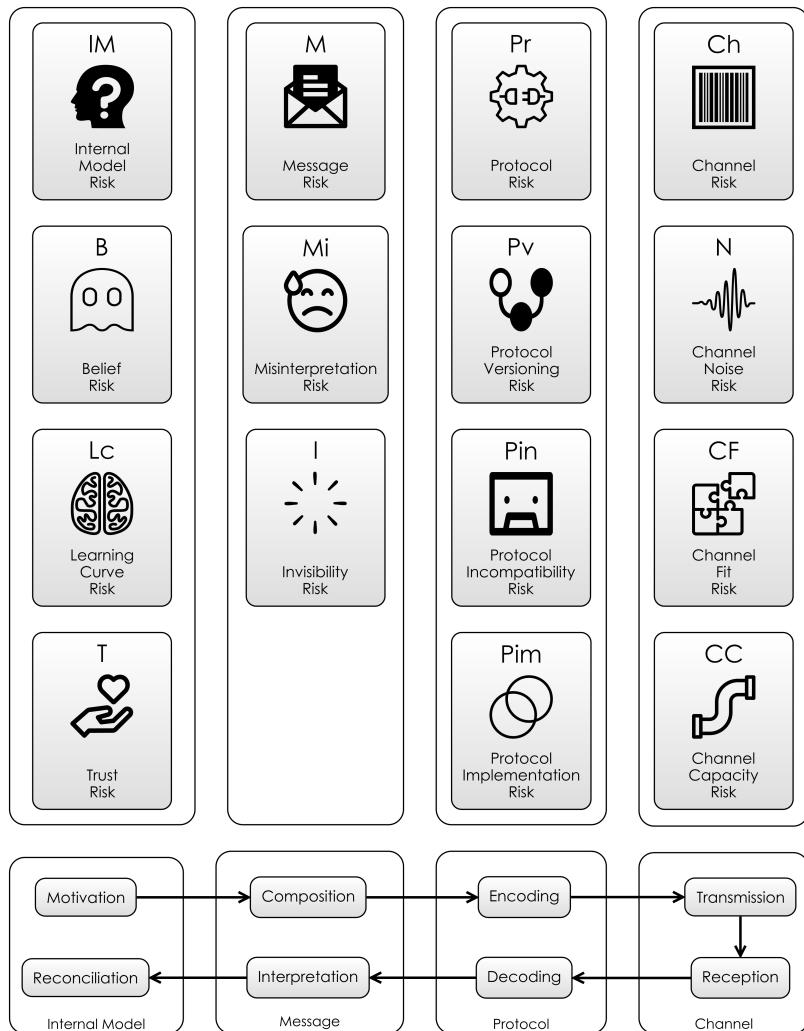

So, here's a summary of where we've arrived with our model of communication risk:

There's no point to Communication unless you have someone or something to communicate with! So next it's time to look at Dependency Risk.

this seems complex tbd.

---

<sup>36</sup>[https://en.wikipedia.org/wiki/Principle\\_of\\_least\\_astonishment](https://en.wikipedia.org/wiki/Principle_of_least_astonishment)

*Figure 5.12: Communication 2*

# Dependency Risk

Dependency Risk is the risk you take on whenever you have a dependency on something (or someone) else. One simple example could be that the software service you write might depend on a server to run on. If the server goes down, the service goes down too. In turn, the server depends on electricity from a supplier, as well as a network connection from a provider. If either of these dependencies aren't met, the service is out of commission.

Dependencies can be on *events, people, teams, processes, software, services, money*: pretty much *any resource*. Dependencies add risk to any project because the reliability of the project itself is now a function involving the reliability of the dependency.

In order to avoid repetition, and also to break down this large topic, we're going to look at this over 6 chapters:

- In this first chapter will look at dependencies *in general*, and specifically on *events*, and some of the variations on Dependency Risk.
- Next, we'll look at Schedule Risk, because time and money are key dependencies in any project.
- Then, we'll move on to look specifically at Software Dependency Risk, covering using libraries, software services and building on top of the work of others.
- After, we'll take a look at Process Risk, which is still Dependency Risk, but we'll be considering more organisational factors and how bureaucracy comes into the picture.
- Next, we'll take a closer look at Boundary Risk and Dead-End Risk. These are the risks you face in choosing the wrong things to depend on.

- Finally, we'll wrap up this analysis with a look at some of the specific problems around working with other people or businesses in Agency Risk.

## 6.1 Why Have Dependencies?

Luckily for us, the things we depend on in life are, for the most part, abundant: water to drink, air to breathe, light, heat and most of the time, food for energy.

This isn't even lucky though: life has adapted to build dependencies on things that it can *rely* on.

Although life exists at the bottom of the ocean around hydrothermal vents<sup>1</sup>, it is a very different kind of life to us, and has a different set of dependencies given it's circumstances.

This tells us a lot about Dependency Risk right here:

- On the one hand, depending on something else is very often helpful, and quite often essential. (For example, all animals that *move* seem to depend on oxygen).
- However, as soon as you have dependencies, you need to take into account of their *reliability*. (Living near a river or stream gives you access to fresh water, for example).
- Successful organisms *adapt* to the dependencies available to them (like the thermal vent creatures).
- There is likely to be *competition* for a dependency when it is scarce (think of droughts and famine).

So, dependencies are a trade-off. They give with one hand and take with the other. Our modern lives are full of dependency (just think of the chains of dependency needed for putting a packet of biscuits on a supermarket shelf, for example), but we accept this extra complexity because it makes life *easier*.

## 6.2 Simple Made Easy

In Rich Hickey's talk, Simple Made Easy<sup>2</sup> he discusses the difference between *simple* software systems and *easy* (to use) ones, heavily stressing the virtues of simple over easy. It's an incredible talk and well worth watching.

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Hydrothermal\\_vent](https://en.wikipedia.org/wiki/Hydrothermal_vent)

<sup>2</sup><https://www.infoq.com/presentations/Simple-Made-Easy>

But. Living systems are not simple. Not anymore. They evolved in the direction of increasing complexity because life was *easier* that way. In the “simpler” direction, life is first *harder* and then *impossible*, and then an evolutionary dead-end.

Depending on things makes *your job easier*. It’s just division of labour<sup>3</sup> and dependency hierarchies, as we saw in Hierarchies and Modularization.

Our economic system and our software systems exhibit the same tendency-towards-complexity. For example, the television in my house now is *vastly more complicated* than the one in my home when I was a child. But, it contains much more functionality and consumes much less power and space.

## 6.3 Event Dependencies

Let’s start with dependencies on *events*.

We rely on events occurring all the time in our lives, and so this is a good place to start in our analysis of Dependency Risk generally. And, as we will see, all the risks that apply to events pretty much apply to all the other kinds of dependencies we’ll look at.

Arguably, the event dependencies are the simplest to express, too: usually, a *time* and a *place*. For example: - “I can’t start shopping until the supermarket opens at 9am”, or - “I must catch my bus to work at 7:30am”.

In the first example, you can’t *start* something until a particular event happens. In the latter example, you must *be ready* for an event at a particular time.

### Events Mitigate Risk...

Having an event occur in a fixed time and place is mitigating risk:

- By taking the bus, we are mitigating our own Schedule Risk: we’re (hopefully) reducing the amount of time we’re going to spend on the activity of getting to work.
- Events are a mitigation for Coordination Risk: A bus needn’t necessarily *have* a fixed timetable: it could wait for each passenger until they turned up, and then go. (A bit like ride-sharing works). This would be a total disaster from a Coordination Risk perspective, as one person could cause everyone else to be really really late. Having a fixed time for doing something mitigates Coordination Risk by turning it into Schedule

---

<sup>3</sup>[https://en.wikipedia.org/wiki/Division\\_of\\_labour](https://en.wikipedia.org/wiki/Division_of_labour)

Risk. Agreeing a date for a product launch, for example, allows lots of teams to coordinate their activities.

- It's not entirely necessary to even take the bus: you could walk, or go by another form of transport. But, effectively, this just swaps one dependency for another: if you walk, this might well take longer and use more energy, so you're just picking up Schedule Risk in another way. If you drive, you have a dependency on your car instead. So, there is often an *opportunity cost* with dependencies. Using the bus might be a cheap way to travel. You're therefore imposing less Dependency Risk on a different scarce resource - your money.

## But, Events Lead To Attendant Risk

By *deciding to use the bus* we've Taken Action.

**Figure 6.1: Action Diagram showing risks mitigated by having an event**

However, as we saw in A Simple Scenario, this means we pick up Attendant Risks.

So, we're going to look at Dependency Risk for our toy events (bus, supermarket) from 7 different perspectives, many of which we've already touched on in the other chapters.

- Schedule Risk
- Reliability Risk
- Scarcity Risk
- Communication Risk
- Complexity Risk
- Feature Fit Risk
- Dead-End Risk and Boundary Risk

(Although you might be able to think of a few more.)

Let's look at each of these in turn.

## 6.4 Schedule Risk

- The aspect of dependency risk related to time.

*Figure 6.2: Schedule Risk*

By agreeing a *time* and *place* for something to happen, you're introducing Deadline Risk. Miss the deadline, and you miss the bus, or the start of the meeting or get fined for not filling your tax return on time.

As discussed above, *schedules* (such as bus timetables) exist so that *two or more parties can coordinate*, and Deadline Risk is on *all* of the parties. While there's a risk I am late, there's also a risk the bus is late. I might miss the start of a concert, or the band might keep everyone waiting.

Each party can mitigate Deadline Risk with *slack*. That is, ensuring that the exact time of the event isn't critical to your plans:

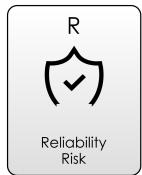

- Don't build into your plans a *need* to start shopping at 9am.
- Arrive at the bus-stop *early*.

The amount of slack you build into the schedule is likely dependent on the level of risk you face: I tend to arrive a few minutes early for a bus, because the risk is *low* (there'll be another bus along soon), however I try to arrive over an hour early for a flight, because I can't simply get on the next flight straight away, and I've already paid for it, so the risk is *high*.

Deadline Risk becomes very hard to manage when you have to coordinate actions with lots of tightly-constrained events. So what else can give? We can reduce the number of *parties* involved in the event, which reduces risk, or, we can make sure all the parties are in the same *place* to begin with.

## 6.5 Reliability Risk

Deadline Risk is really a kind of reliability issue: if you can understand which parties are unreliable, you have a much better handle on your Deadline Risk.

- Risks of not getting benefit from a dependency due to it's reliability.

*Figure 6.3: Reliability Risk*

Luckily, there is quite a lot of existing science around reliability. For example:

- If a component **A** depends on component **B**, unless there is some extra redundancy around **B**, then **A** can't be more reliable than **B**.
- Is **A** or **B** a Single Point Of Failure<sup>4</sup> in a system?
- Are there bugs in **B** that are going to prevent it working correctly in all circumstances?

This kind of stuff is encapsulated in the science of Reliability Engineering<sup>5</sup>. For example, Failure mode and effects analysis (FEMA)<sup>6</sup>:

“... was one of the first highly structured, systematic techniques for failure analysis. It was developed by reliability engineers in the late 1950s to study problems that might arise from malfunctions of military systems.” - FEMA, Wikipedia

This was applied on NASA missions, and then more recently in the 1970's to car design following the Ford Pinto exploding car<sup>7</sup> affair.

## 6.6 Scarcity Risk

Let's get back to the bus (which, hopefully, is still working). What if, when it arrives, it's already full of passengers? Let's term this, Scarcity Risk - the chance that a dependency is over-subscribed and you can't use it the way you want. This is clearly an issue for nearly every kind of dependency: buses, supermarkets, concerts, teams, services and people.

<sup>4</sup>[https://en.wikipedia.org/wiki/Single\\_point\\_of\\_failure](https://en.wikipedia.org/wiki/Single_point_of_failure)

<sup>5</sup>[https://en.wikipedia.org/wiki/Reliability\\_engineering](https://en.wikipedia.org/wiki/Reliability_engineering)

<sup>6</sup>[https://en.wikipedia.org/wiki/Failure\\_mode\\_and\\_effects\\_analysis](https://en.wikipedia.org/wiki/Failure_mode_and_effects_analysis)

<sup>7</sup>[https://en.wikipedia.org/wiki/Ford\\_Pinto#Design\\_flaws\\_and\\_ensuing\\_lawsuits](https://en.wikipedia.org/wiki/Ford_Pinto#Design_flaws_and_ensuing_lawsuits)

- Risk of not being able to access a dependency in a timely fashion due to its scarcity.

*Figure 6.4: Scarcity Risk*

You could also call this *availability risk* or *capacity risk* of the resource. Here are a selection of mitigations:

- **Buffers:** Smoothing out peaks and troughs in utilisation.
- **Reservation Systems:** giving clients information *ahead* of the dependency usage about whether the resource will be available to them.
- **Graceful degradation:** Ensuring *some* service in the event of over-subscription. It would be no use allowing people to cram onto the bus until it can't move.
- **Demand Management:** Having different prices during busy periods helps to reduce demand. Having "first class" seats means that higher-paying clients can get service even when the train is full. Uber<sup>8</sup> adjust prices in real-time by so-called Surge Pricing<sup>9</sup>. This is basically turning Scarcity Risk into a Market Risk problem.
- **Queues:** Again, these provide a "fair" way of dealing with scarcity by exposing some mechanism for prioritising use of the resource. Buses operate a first-come-first-served system, whereas emergency departments in hospitals triage according to need.
- **Pools:** Reserving parts of a resource for particular customers.
- **Horizontal Scaling:** allowing a scarce resource to flexibly scale according to how much demand there is. (For example, putting on extra buses when the trains are on strike, or opening extra check-outs at the supermarket.)

Much like Reliability Risk, there is science for it:

- Queue Theory<sup>10</sup> is all about building mathematical models of buffers, queues, pools and so forth.

---

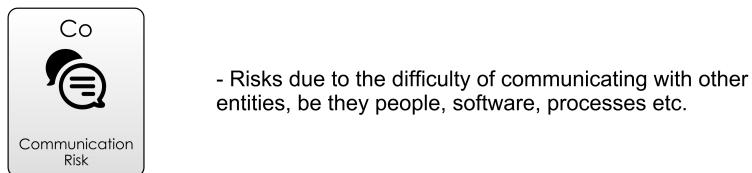

<sup>8</sup><https://www.uber.com>

<sup>9</sup><https://www.uber.com/en-GB/drive/partner-app/how-surge-works/>

<sup>10</sup>[https://en.wikipedia.org/wiki/Queueing\\_theory](https://en.wikipedia.org/wiki/Queueing_theory)

- Logistics<sup>11</sup> is the practical organisation of the flows of materials and goods around things like Supply Chains<sup>12</sup>.
- And Project Management<sup>13</sup> is in large part about ensuring the right resources are available at the right times. We'll be taking a closer look at that in the Part 3 chapters on Prioritisation and the Project Management Body Of Knowledge.

## 6.7 Communication Risk

*Figure 6.5: Communication Risk*

We've already looked at communication risk in a lot of depth, and we're going to go deeper still in Software Dependency Risk, but let's look at some general issues around communicating dependencies. In the Communication Risk chapter we looked at Marketing Communications and talked about the levels of awareness that you could have with dependencies. i.e.

- The concept that there is such a thing as **D** which solves my problem isn't something I'd even considered.
- I'd like to use something like **D**, but how do I find it?
- There are multiple implementations of **D**, which is the best one for the task?
- I know **D**, but I can't figure out how to solve my problem in it.

Let's apply this to our Bus scenario:

- Am I aware that there is public transport in my area?
- How do I find out about the different options?
- How do I choose between buses, taxis, cars etc.
- How do I understand the timetable, and apply it to my problem?

---

<sup>11</sup><https://en.wikipedia.org/wiki/Logistics>

<sup>12</sup>[https://en.wikipedia.org/wiki/Supply\\_chain](https://en.wikipedia.org/wiki/Supply_chain)

<sup>13</sup>[https://en.wikipedia.org/wiki/Project\\_management](https://en.wikipedia.org/wiki/Project_management)

## Silo Mentality

Finding out about bus schedules is easy. But in a large company, Communication Risk and especially Invisibility Risk are huge problems. This tends to get called “Silo Mentality<sup>14</sup>”, that is, ignoring what else is going on in other divisions of the company or “not invented here”<sup>15</sup> syndrome:

“In management the term silo mentality often refers to information silos in organizations. Silo mentality is caused by divergent goals of different organizational units.” - Silo Mentality, *Wikipedia*

Ironically, *more communication* might not be the answer - if channels are provided to discover functionality in other teams you can still run into Trust Risk (why should I believe in the quality of this dependency?) Or Channel Risk in terms of too low a signal-to-noise ratio, or desperate self-promotion.

Silo Mentality is exacerbated by the problems you would face in *budgeting* if suddenly all the divisions in an organisation started providing dependencies for each other. This starts to require a change to organisational structure towards being a set of individual businesses marketing services to one another, rather than a division-based one. We’ll look more closely at these kind of organisational issues in the Coordination Risk chapter.

## 6.8 Complexity Risk

Dependencies are usually a mitigation for Complexity Risk, and we’ll investigate that in much more detail in Software Dependency Risk. The reason for this is that a dependency gives you an abstraction: you no longer need to know *how* to do something, (that’s the job of the dependency), you just need to interact with the dependency properly to get the job done. Buses are *perfect* for people who can’t drive, after all.

But this means that all of the issues of abstractions that we covered in Communication Risk apply:

- There is Invisibility Risk because you probably don’t have a full view of what the dependency is doing. Nowadays, bus stops have a digital “arrivals” board which gives you details of when the bus will arrive, and shops publish their opening hours online. But, abstraction always means the loss of some detail.

---

<sup>14</sup>[https://en.wikipedia.org/wiki/Information\\_silo#Silo\\_mentality](https://en.wikipedia.org/wiki/Information_silo#Silo_mentality)

<sup>15</sup>[https://en.wikipedia.org/wiki/Not\\_invented\\_here](https://en.wikipedia.org/wiki/Not_invented_here)

- There is Misinterpretation Risk, because often the dependency might mistake your instructions. This is endemic in software, where it's nearly impossible to describe exactly what you want up-front.

## 6.9 Fit Risk

- Risks you face when providing features for your clients.

*Figure 6.6: Feature Fit Risk*

Sometimes, the bus will take you to lots of in-between places you *didn't* want to go. This is Fit Risk and we saw this already in the chapter on Feature Risk. There, we considered two problems:

- The feature (or now, dependency) doesn't provide all the functionality you need. This was Fit Risk. An example might be the supermarket not stocking everything you wanted.
- The feature / dependency provides far too much, and you have to accept more complexity than you need. This was Conceptual Integrity Risk. An example of this might be the supermarket being *too big*, and you spend a lot longer navigating it than you wanted to.

## 6.10 Dead-End Risk and Boundary Risk

When you choose something to depend on, you can't be certain that it's going to work out in your favour. Sometimes, the path from your starting point to your goal on the Risk Landscape will take you to dead ends: places where the only way towards your destination is to lose something, and do it again another way. This is Dead End Risk, which we looked at before.

Boundary Risk is another feature of the Risk Landscape: when you make a decision to use one dependency over another, you are picking a path on the risk landscape that *precludes* other choices. After all, there's not really much cost in a Dead End if you've not had to follow a path to get to it.

*Figure 6.7: Feature Fit: A Two-Dimensional Problem (at least)*

We're also going to look at Boundary Risk in more detail later, but I want to introduce it here. Here are some examples:

- If I choose to program some software in Java, I will find it hard to integrate libraries from other languages. The dependencies available to Java software are different to those in Javascript, or C#. Having gone down a Java route, there are *higher risks* associated with choosing incompatible technologies. Yes, I can pick dependencies that use C# (still), but I am now facing greater complexity risk than if I'd just chosen to do everything in C# in the first place.
- If I choose one database over another, I am *limited to the features of that database*. This is not the same as a dead-end: I can probably build what I want to build, but the solution will be "bounded" by the dependency choices I make. One of the reasons we have standards like Java Database Connectivity (JDBC)<sup>16</sup> is to mitigate Dead End Risk around databases, so that we can move to a different database later.
- If I choose to buy a bus ticket, I've made a decision not to travel by train, even though later on it might turn out that the train was a better option. Buying the bus ticket is Boundary Risk: I may be able to get a refund, but having chosen the dependency I've set down a path on the risk landscape.

---

<sup>16</sup>[https://en.wikipedia.org/wiki/Java\\_Database\\_Connectivity](https://en.wikipedia.org/wiki/Java_Database_Connectivity)

## 6.11 Managing Dependency Risk

Arguably, managing Dependency Risk is *what Project Managers do*. Their job is to meet the Goal by organising the available dependencies into some kind of useful order.

There are *some* tools for managing dependency risk: Gantt Charts<sup>17</sup> for example, arrange work according to the capacity of the resources (i.e. dependencies) available, but also the *dependencies between the tasks*. If task **B** requires the outputs of task **A**, then clearly task **A** comes first and task **B** starts after it finishes. We'll look at this more in Process Risk.

We'll look in more detail at project management in the *practices* part, later. But now let's get into the specifics with Schedule Risk.

---

<sup>17</sup>[https://en.wikipedia.org/wiki/Gantt\\_chart](https://en.wikipedia.org/wiki/Gantt_chart)

## Schedule Risk

Schedule Risk is the term for risks you face because of *lack of time*.

You could also call this “Chronological Risk” or just “Time Risk” if you wanted to.

- The aspect of dependency risk related to time.

*Figure 7.1: Schedule Risk*

Schedule Risk is very pervasive, and really underlies *everything* we do. People *want* things, but they *want them at a certain time*. We need to eat and drink every day, for example. We might value having a great meal, but not if we have to wait three weeks for it.

And let's go completely philosophical for a second: Were you to attain immortality, you'd probably not feel the need to buy *anything*. You'd clearly have no *needs*, and anything you wanted, you could create yourself within your infinite time-budget. Rocks don't need money, after all.

Let's look at some specific kinds of Schedule Risk.

*Figure 7.2: Opportunity Risk*

## 7.1 Opportunity Risk

Opportunity Risk is really the concern that whatever we do, we have to do it *in time*. If we wait too long, we'll miss the Window Of Opportunity<sup>1</sup> for our product or service.

Any product idea is necessarily of its time: the Goal In Mind will be based on observations from a particular Internal Model, reflecting a view on reality at a specific *point in time*.

How long will that remain true for? This is your *opportunity*: it exists apart from any deadlines you set yourself, or funding options. It's purely, "how long will this idea be worth doing?"

With any luck, decisions around *funding* your project will be tied into this, but it's not always the case. It's very easy to undershoot or overshoot the market completely and miss the window of opportunity.

### The iPad

For example, let's look at the iPad<sup>2</sup>, which was introduced in 2010 and was hugely successful.

This was not the first tablet computer. Apple had already tried to introduce the Newton<sup>3</sup> in 1989, and Microsoft had released the Tablet PC<sup>4</sup> in 1999. But somehow, they both missed the Window Of Opportunity. Possibly, the window existed because Apple had changed the market with their release of the iPhone, which left people open to the idea of a tablet being "just a bigger iPhone".

<sup>1</sup>[https://en.wikipedia.org/wiki/Window\\_of\\_opportunity](https://en.wikipedia.org/wiki/Window_of_opportunity)

<sup>2</sup>[https://en.wikipedia.org/wiki/History\\_of\\_tablet\\_computers](https://en.wikipedia.org/wiki/History_of_tablet_computers)

<sup>3</sup>[https://en.wikipedia.org/wiki/Apple\\_Newton](https://en.wikipedia.org/wiki/Apple_Newton)

<sup>4</sup>[https://en.wikipedia.org/wiki/Microsoft\\_Tablet\\_PC](https://en.wikipedia.org/wiki/Microsoft_Tablet_PC)

But maybe now, the iPad's window is closing? We have more *wearable computers* like the Apple Watch<sup>5</sup>, and voice-controlled devices like Alexa<sup>6</sup> or Siri<sup>7</sup>. Peak iPad was in 2014, according to this graph<sup>8</sup>.

So, it seems Apple timed the iPad to hit the peak of the Window of Opportunity.

But, even if you time the Window Of Opportunity correctly, you might still have the rug pulled from under your feet due to a different kind of Schedule Risk, such as...

## 7.2 Deadline Risk

- Where the use of a dependency has some kind of deadline, which can be missed.

*Figure 7.3: Deadline Risk*

Often when running a software project, you're given a team of people and told to get something delivered by a certain date. i.e. you have an artificially-imposed Deadline on delivery.

What happens if you miss the deadline? It could be:

- The funding on the project runs out, and it gets cancelled.
- You have to go back to a budgeting committee, and get more money.
- The team gets replaced, because of lack of faith.

.. or something else.

Deadlines can be set by an authority in order to *sharpen focus* and reduce Coordination Risk. This is how we arrive at tools like SMART Objectives<sup>9</sup> and KPI's (Key Performance Indicators)<sup>10</sup>. Time scales change the way we evaluate goals, and the solutions we choose.

---

<sup>5</sup>[https://en.wikipedia.org/wiki/Apple\\_Watch](https://en.wikipedia.org/wiki/Apple_Watch)

<sup>6</sup>[https://en.wikipedia.org/wiki/Amazon\\_Alexa](https://en.wikipedia.org/wiki/Amazon_Alexa)

<sup>7</sup><https://en.wikipedia.org/wiki/Siri>

<sup>8</sup><https://www.statista.com/statistics/269915/global-apple-ipad-sales-since-q3-2010/>

<sup>9</sup>[https://en.wikipedia.org/wiki/SMART\\_criteria](https://en.wikipedia.org/wiki/SMART_criteria)

<sup>10</sup>[https://en.wikipedia.org/wiki/Performance\\_indicator](https://en.wikipedia.org/wiki/Performance_indicator)

In JFK's quote:

"First, I believe that this nation should commit itself to achieving the goal, before this decade is out, of landing a man on the moon and returning him safely to the Earth." - John F. Kennedy, 1961

The 9-year timespan came from an authority figure (the president) and helped a huge team of people coordinate their efforts and arrive at a solution that would work within a given time-frame.

Compare with this quote:

"I love deadlines. I love the whooshing noise they make as they go by." - Douglas Adams<sup>11</sup>

As a successful author, Douglas Adams *didn't really care* about the deadlines his publisher's gave him. The Deadline Risk was minimal for him, because the publisher wouldn't be able to give his project to someone else to complete.

Sometimes, deadlines are set in order to *coordinate work between teams*. The classic example being in a battle, to coordinate attacks. When our deadlines are for this purpose, we're heading towards Coordination Risk territory.

## Student Syndrome

Student Syndrome<sup>12</sup> is, according to Wikipedia:

"Student syndrome refers to planned procrastination, when, for example, a student will only start to apply themselves to an assignment at the last possible moment before its deadline." - *Wikipedia*

Arguably, there is good psychological, evolutionary and risk-based reasoning behind procrastination: the further in the future the Deadline Risk is, the more we discount it. If we're only ever mitigating our *biggest risks*, then deadlines in the future don't matter so much, do they? And, putting efforts into mitigating future risks that *might not arise* is wasted effort.

Or at least, that's the argument. If you're Discounting the Future To Zero then you'll be pulling all-nighters in order to deliver any assignment.

---

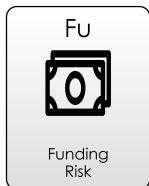

<sup>11</sup>[https://en.wikipedia.org/wiki/Douglas\\_Adams](https://en.wikipedia.org/wiki/Douglas_Adams)

<sup>12</sup>[https://en.wikipedia.org/wiki/Student\\_syndrome](https://en.wikipedia.org/wiki/Student_syndrome)

So, the problem with Student Syndrome is that the *very mitigation* for Schedule Risk (allowing more time) is an Attendant Risk that *causes* Schedule Risk: you'll work towards the new, generous deadline more slowly, and you'll end up revealing Hidden Risk *later* than you would have with the original, pressing deadline ... and you end up being late because of them.

We'll look at mitigations for this in Part 3's chapter on Prioritisation.

## 7.3 Funding Risk

- A particular scarcity risk, due to lack of funding.

*Figure 7.4: Funding Risk*

On a lot of software projects, you are “handed down” deadlines from above, and told to deliver by a certain date or face the consequences. But sometimes you’re given a budget instead, which really just adds another layer of abstraction to the Schedule Risk: That is, do I have enough funds to cover the team for as long as I need them?

This grants you some leeway as now you have two variables to play with: the *size* of the team, and *how long* you can run it for. The larger the team, the shorter the time you can afford to pay for it.

In startup circles, this “amount of time you can afford it” is called the “Runway”<sup>13</sup>: you have to get the product to “take-off” before the runway ends. So you could term this component as “Runway Risk”.

Startups often spend a lot of time courting investors in order to get funding and mitigate this type of Schedule Risk. But, this activity usually comes at the expense of Opportunity Risk and Feature Risk, as usually the same people are trying to raise funds as build the project itself.

- The aspect of dependency risks related to employing people.

*Figure 7.5: Staff Risk*

## 7.4 Staff Risk

If a startup has a “Runway”, then the chances are that the founders and staff do too, as this article explores<sup>14</sup>. It identifies the following risks:

- Company Cash: The **Runway** of the startup itself
- Founder Cash: The **Runway** for a founder, before they run out of money and can't afford their rent.
- Team Cash: The **Runway** for team members, who may not have the same appetite for risk as the founders do.

You need to consider how long your staff are going to be around, especially if you have Key Man Risk<sup>15</sup> on some of them. People like to have new challenges, or move on to live in new places, or simply get bored. The longer your project goes on for, the more Staff Risk you will have to endure, and you can't rely on getting the best staff for failing projects.

In the chapter on Coordination-Risk we'll look in more detail at the non-temporal components of Staff Risk.

## 7.5 Red-Queen Risk

A more specific formulation of Schedule Risk is Red Queen Risk, which is that whatever you build at the start of the project will go slowly more-and-more out of date as the project goes on.

This is named after the Red Queen quote from Alice in Wonderland:

<sup>13</sup><https://en.wiktionary.org/wiki/runway>

<sup>14</sup><https://www.entrepreneur.com/article/223135>

<sup>15</sup>[https://en.wikipedia.org/wiki/Key\\_person\\_insurance#Key\\_person\\_definition](https://en.wikipedia.org/wiki/Key_person_insurance#Key_person_definition)

- The general risk that the competitive environment we operate within changes over time.

*Figure 7.6: Red Queen Risk*

“My dear, here we must run as fast as we can, just to stay in place. And if you wish to go anywhere you must run twice as fast as that.” - Lewis Carroll, *Alice in Wonderland*<sup>16</sup>

The problem with software projects is that tools and techniques change *really fast*. In 2011, 3DRealms released Duke Nukem Forever after 15 years in development<sup>17</sup>, to negative reviews:

“... most of the criticism directed towards the game’s long loading times, clunky controls, offensive humor, and overall aging and dated design.” - *Duke Nukem Forever*, Wikipedia

Now, they didn’t *deliberately* take 15 years to build this game (lots of things went wrong). But, the longer it took, the more their existing design and code-base were a liability rather than an asset.

Personally, I have suffered the pain on project teams where we’ve had to cope with legacy code and databases because the cost of changing them was too high. And any team who is stuck using Visual Basic 6.0<sup>18</sup> is here. It’s possible to ignore Red Queen Risk for a time, but this is just another form of Technical Debt which eventually comes due.

## 7.6 Schedule Risk and Feature Risk

In the chapter on Feature Risk we looked at Market Risk, the idea that the value of your product is itself at risk from the morsés of the market, share prices being the obvious example of that effect. In Finance, we measure

<sup>16</sup><https://www.goodreads.com/quotes/458856-my-dear-here-we-must-run-as-fast-as-we>

<sup>17</sup>[https://en.wikipedia.org/wiki/Duke\\_Nukem\\_Forever](https://en.wikipedia.org/wiki/Duke_Nukem_Forever)

<sup>18</sup>[https://en.wikipedia.org/wiki/Visual\\_Basic](https://en.wikipedia.org/wiki/Visual_Basic)

this using *money*, and we can put together probability models based on how much money you might make or lose.

With Schedule Risk, the underlying measure is *time*:

- “If I implement feature X, I’m picking up something like 5 days of Schedule Risk.”
- “If John goes travelling that’s going to hit us with lots of Schedule Risk while we train up Anne.”

... and so on. Clearly, in the same way as you don’t know exactly how much money you might lose or gain on the stock-exchange, you can’t put precise numbers on Schedule Risk either.

Schedule Risk, then, is *fundamental* to every dependency. But now it’s time to get into the *specifics*, and look at Software Dependencies.

# Software Dependency Risk

In this chapter, we're going to look specifically at *Software* dependencies, although many of the concerns we'll raise here apply equally to all the other types of dependency we outlined in Dependency Risk.

## 8.1 Kolmogorov Complexity: Cheating

In the earlier chapter on Complexity Risk we tackled Kolmogorov Complexity, and the idea that your codebase had some kind of minimal level of complexity based on the output it was trying to create. This is a neat idea, but in a way, we cheated. Let's look at how.

We were trying to figure out the shortest (Javascript) program to generate this output:

```
abcdabcdabcdabcdabcdabcdabcdabcdabcd
```

And we came up with this:

```
const ABCD="ABCD";           (11 symbols)

function out() {
    return ABCD.repeat(10)   (7 symbols)
}                           (1 symbol)
```

Which had **26** symbols in it.

Now, here's the cheat: The `repeat()` function was built into Javascript in 2015 in ECMAScript 6.0<sup>1</sup>. If we'd had to program it ourselves, we might have

---

<sup>1</sup><http://www.ecma-international.org/ecma-262/6.0/>

added this:

```
function repeat(s,n) {          (10 symbols)
    var a=[];                  (7 symbols)
    while(a.length<n){        (9 symbols)
        a.push(s)              (6 symbols)
    }                          (1 symbol)
    return a.join('');         (10 symbols)
}                                (1 symbol)
```

... which would be an extra **44** symbols (in total **70**), and push us completely over the original string encoding of **53** symbols. So, *encoding language is important.*

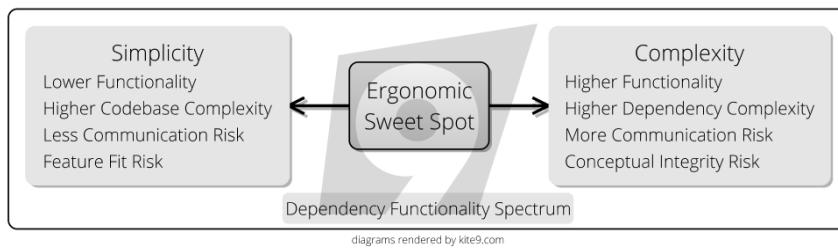

Conversely, if ECMAScript 6.0 had introduced a function called `abcdRepeater(n)` we'd have been able to do this:

```
function out() {                (7 symbols)
    return abcdRepeater(10)      (6 symbols)
}                                (1 symbol)
```

.. and re-encode to **14** symbols. Now, clearly there are some problems with all this:

1. Clearly, *language matters*: the Kolmogorov complexity is dependent on the language, and the features the language has built in.
2. The exact Kolmogorov complexity is uncomputable anyway (it's the *theoretical* minimum program length). It's just a fairly abstract idea, so we shouldn't get too hung up on this. There is no function to be able to say, "what's the Kolmogorov complexity of string X"
3. What is this new library function we've created? Is `abcdRepeater` going to be part of *every* Javascript? If so, then we've shifted Codebase Risk away from ourselves, but we've pushed Communication Risk and Dependency Risk onto every *other* user of Javascript. (Why these? Because `abcdRepeater` will be clogging up the documentation and other people will rely on it to function correctly.)
4. Are there equivalent functions for every single other string? If so, then compilation is no longer a tractable problem: is `return abcdRepeater(10)` correct code? Well, now we have a massive library of different `XXXRepeater` functions to compile against to see if it is... So, what we *lose* in Kolmogorov Complexity we gain in Runtime Complexity.

5. Language design, then, is about *ergonomics*. After you have passed the relatively low bar of providing Turing Completeness<sup>2</sup>, the key is to provide *useful* features that enable problems to be solved, without over-burdening the user with features they *don't* need. And in fact, all software is about this.

*Figure 8.1: Software Dependency Ergonomics: finding the sweet spot between too many features and too few*

## 8.2 Ergonomics Examined

Have a look at some physical tools, like a hammer, or spanner. To look at them, they are probably *simple* objects, obvious, strong and dependable. Their entire behaviour is encapsulated in their form. Now, if you have a drill or sander to hand, look at the design of this too. If it's well-designed, then from the outside it is simple, perhaps with only one or two controls. Inside, it is complex and contains a motor, perhaps a transformer, and is maybe made of a hundred different components.

But outside, the form is simple, and designed for humans to use. This is *ergonomics*<sup>3</sup>:

"Human factors and ergonomics (commonly referred to as Human Factors), is the application of psychological and physiological principles to the (engineering and) design of products, processes, and systems. The goal of human factors is to reduce human error, increase productivity, and enhance safety and comfort with a specific focus on the interaction between the human and the thing of interest." - Human Factors and Ergonomics, Wikipedia

<sup>2</sup>[https://en.wikipedia.org/wiki/Turing\\_completeness](https://en.wikipedia.org/wiki/Turing_completeness)

<sup>3</sup>[https://en.wikipedia.org/wiki/Human\\_factors\\_and\\_ergonomics](https://en.wikipedia.org/wiki/Human_factors_and_ergonomics)

## Interfaces

The interface of a tool is the part we touch and interact with. By striving for simplicity, the interface reduces Communication Risk.

The interface of a system expands when you ask it to do a wide variety of things. An easy-to-use drill does one thing well: it turns drill-bits at useful levels of torque for drilling holes and sinking screws. But if you wanted it to also operate as a lathe, a sander or a strimmer (all basically mechanical things going round) you would have to sacrifice the ergonomic simplicity for a more complex interface, probably including adapters, extensions, handles and so on.

So, we now have split complexity into two: - The inner complexity of the tool (how it works internally, it's own Kolmogorov Complexity). - The complexity of the instructions that we need to write to make the tool work (the interface Kolmogorov Complexity).

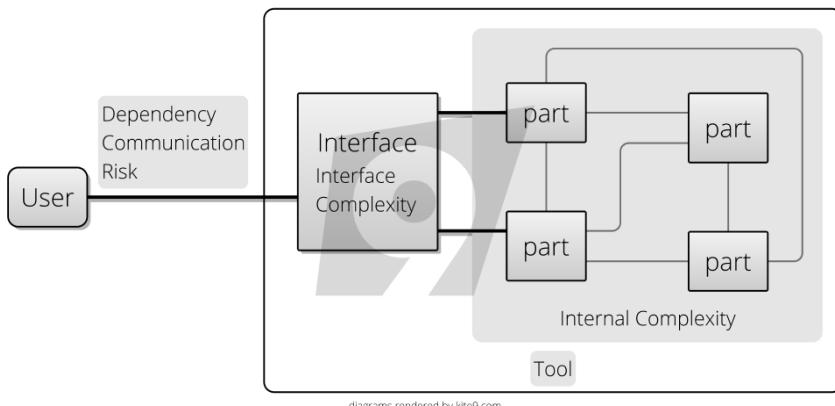

Figure 8.2: Types of Complexity For a Software Dependency

## Software Tools

In the same way as with a hand-tool, the bulk of the complexity of a software tool is hidden behind its interface. But, the more complex the *purpose* of the tool, the more complex the interface will be.

Software is not constrained by *physical* ergonomics in the same way as a tool is. But ideally, it should have conceptual ergonomics: ideally, complexity is hidden away from the user behind the Application Programming Interface (API)<sup>4</sup>. This is the familiar concept of Abstraction we've already looked at.

<sup>4</sup>[https://en.wikipedia.org/wiki/Application\\_programming\\_interface](https://en.wikipedia.org/wiki/Application_programming_interface)

That is, the tool should be as simple to use and understand as possible. This is the Principal Of Least Astonishment:

- **The abstractions should map easily to how the user expects the tool to work.** For example, I *expect* the trigger on a drill to start the drill turning.
- **The abstractions should leverage existing idioms and knowledge.** In a new car, I *expect* to know what the symbols on the dashboard mean, because I've driven other cars.
- **The abstractions provide me with only the functions I need.** Because everything else is confusing and gets in the way.

The way to win, then, is to allow a language to be extensible as-needed with features written by third parties. By supplying mechanisms for extension a language can provide insurances against the Boundary Risk of adopting it.

## 8.3 Types Of Software Dependencies

There are lots of ways you can depend on software. Here though, we're going to focus on just three main types: 1. **Code Your Own**: write some code ourselves to meet the dependency. 2. **Software Libraries**: importing code from the Internet, and using it in our project. Often, libraries are Open Source (this is what we'll consider here). 3. **Software as a Service**: calling a service on the Internet, (probably via `http`) This is often known as SaaS, or Software as a Service<sup>5</sup>.

All 3 approaches involve a different risk-profile. Let's look at each in turn, from the perspective of which risks get mitigated, and which risks are accentuated.

### 1. Code Your Own

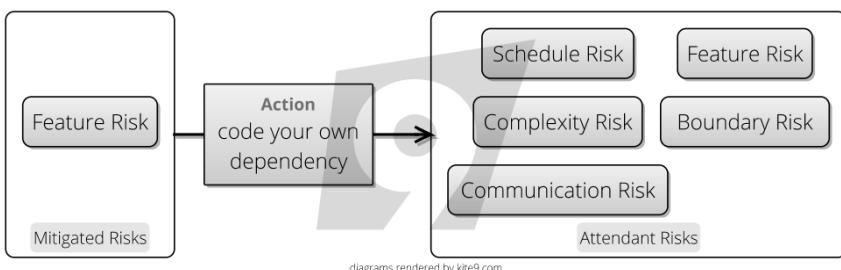

Initially, writing our own code was the only game in town: when I started programming, you had a user guide, BASIC and that was pretty much it. Tool support was very thin-on-the-ground. Programs and libraries could be distributed as code snippets *in magazines* which could be transcribed and run, and added to your program. This spirit lives on somewhat in StackOverflow and JSFiddle, where you are expected to "adopt" others' code into your own project.

---

<sup>5</sup>[https://en.wikipedia.org/wiki/Software\\_as\\_a\\_service](https://en.wikipedia.org/wiki/Software_as_a_service)

One of the hidden risks of embarking on a code-your-own approach is that the features you need are *not* apparent from the outset. What might appear to be a trivial implementation of some piece of functionality can often turn into its own industry as more and more hidden Feature Risk is uncovered.

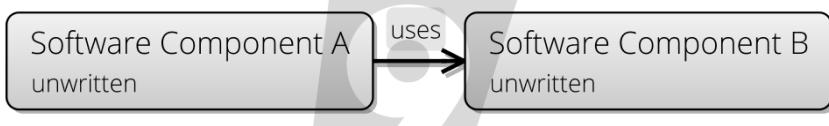

For example, as we discussed in our earlier treatment of Dead-End Risk, building log-in screens *seemed like a good idea*. However, this gets out-of-hand fast when you need: - A password reset screen - To email the reset links to the user - An email verification screen - A lost account screen - Reminders to complete the sign up process - . . . and so on.

*Figure 8.3: Code-Your-Own mitigates immediate feature risk, but at the expense of schedule risk, complexity risk and communication risk. There is also a hidden risk of features you don't yet know you need.*

## Unwritten Software

Sometimes, you will pick up a dependency on *unwritten software*. This commonly happens when work is divided amongst team members, or teams.

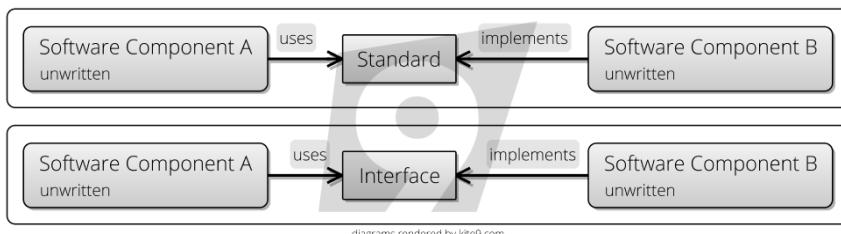

*Figure 8.4: Sometimes, a module you're writing will depend on unwritten code*

If a component **A** of our project *depends on B* for some kind of processing, you might not be able to complete **A** before writing **B**. This makes *scheduling* the project harder, and if component **A** is a risky part of the project, then the chances are you'll want to mitigate risk there first.

But it also hugely increases Communication Risk because now you're being asked to communicate with a dependency that doesn't really exist yet, *let alone* have any documentation.

There are a couple of ways to do this:

- **Standards:** If component **B** is a database, a queue, mail gateway or something else with a standard interface, then you're in luck. Write **A** to those standards, and find a cheap, simple implementation to test with. This gives you time to sort out exactly what implementation of **B** you're going for. This is not a great long-term solution, because obviously, you're not using the *real* dependency- you might get surprised when the behaviour of the real component is subtly different. But it can reduce Schedule Risk in the short-term.
- **Coding To Interfaces:** If standards aren't an option, but the surface area of **B** that **A** uses is quite small and obvious, you can write a small interface for it, and work behind that, using a Mock<sup>6</sup> for **B** while you're waiting for finished component. Write the interface to cover only what **A needs**, rather than everything that **B does** in order to minimize the risk of Leaky Abstractions<sup>7</sup>.

*Figure 8.5: Coding to a standard on an interface breaks the dependency on unwritten software*

## Conway's Law

If the dependency is being written by another person, another team or in another country, communication risks pile up. When this happens, you will want to minimize *as much as possible* the interface complexity, since the more complex the interface, the worse the Communication Risk will be. The tendency then is to make the interfaces between teams or people *as simple as possible*, modularizing along these organisational boundaries.

<sup>6</sup>[https://en.wikipedia.org/wiki/Mock\\_object](https://en.wikipedia.org/wiki/Mock_object)

<sup>7</sup>[https://en.wikipedia.org/wiki/Leaky\\_abstraction](https://en.wikipedia.org/wiki/Leaky_abstraction)

In essence, this is Conway's Law<sup>8</sup>:

"organizations which design systems . . . are constrained to produce designs which are copies of the communication structures of these organizations." —M. Conway, *Conway's Law*

## 2. Software Libraries

By choosing a particular software library, we are making a move on the Risk Landscape in the hope of moving to place with more favourable risks. Typically, using library code offers a Schedule Risk and Complexity Risk Silver Bullet. But, in return we expect to pick up: - Communication Risk: because we now have to learn how to communicate with this new dependency. - Boundary Risk - because now are limited to using the functionality provided by this dependency. We have chosen it over alternatives and changing to something else would be more work and therefore costly.

But, it's quite possible that we could wind up in a worse place than we started out, by using a library that's out-of-date, riddled with bugs or badly supported. i.e. Full of new, hidden Feature Risk.

It's *really easy* to make bad decisions about which tools to use because the tools don't (generally) advertise their deficiencies. After all, they don't generally know how *you* will want to use them.

### Software Libraries - Hidden Risks

Currently, choosing software dependencies looks like a "bounded rationality"-type process:

"Bounded rationality is the idea that when individuals make decisions, their rationality is limited by the tractability of the decision problem, the cognitive limitations of their minds, and the time available to make the decision." - Bounded Rationality, *Wikipedia*<sup>9</sup>

Unfortunately, we know that most decisions *don't* really get made this way. We have things like Confirmation Bias<sup>10</sup> (looking for evidence to support a

---

<sup>8</sup>[https://en.wikipedia.org/wiki/Conway%27s\\_law](https://en.wikipedia.org/wiki/Conway%27s_law)

<sup>9</sup>[https://en.wikipedia.org/wiki/Bounded\\_rationality](https://en.wikipedia.org/wiki/Bounded_rationality)

<sup>10</sup>[https://en.wikipedia.org/wiki/Confirmation\\_bias](https://en.wikipedia.org/wiki/Confirmation_bias)

decision you've already made) and Cognitive Inertia<sup>11</sup> (ignoring evidence that would require you to change your mind) to contend with.

But, leaving that aside, let's try to build a model of what this decision making process *should* involve. Luckily, other authors have already considered the problem of choosing good software libraries, so let's start there.

In the table below, I am summarizing three different sources (linked at the end of the chapter), which give descriptions of which factors to look for when choosing open-source libraries.

Some take-aways:

- Feature Risk is a big concern. How can you be sure that the project will do what you want it to do ahead of schedule? Will it contain bugs or missing features? By looking at factors like *release frequency* and *size of the community* you get a good feel for this which is difficult to fake.
- Boundary Risk is also very important. You are going to have to *live* with your choices for the duration of the project, so it's worth spending the effort to either ensure that you're not going to regret the decision, or that you can change direction later.
- Third is Communication Risk: how well does the project deal with its users? If a project is “famous”, then it has communicated its usefulness to a wide, appreciative audience. Avoiding Communication Risk is also a good reason to pick *tools you are already familiar with*.

## Complexity Risk?

One thing that none of the sources consider (at least from the outset) is the Complexity Risk of using a solution: - Does it drag in lots of extra dependencies that seem unnecessary for the job in hand? If so, you could end up in Dependency Hell<sup>12</sup>, with multiple, conflicting versions of libraries in the project. - Do you already have a dependency providing this functionality? So many times, I've worked on projects that import a *new* dependency when some existing (perhaps transitive) dependency has *already brought in the functionality*. For example, there are plenty of libraries for JSON<sup>13</sup> marshalling, but if I'm also using a web framework the chances are it already has a dependency on one already. - Does it contain lots of functionality that isn't relevant to the task you want it to accomplish? e.g. Using Java when a shell script would do (on a non-Java project)

---

<b>Totals</b>	<b>1</b>	<b>9</b>	<b>15</b>	<b>8</b>	

*Figure 8.6: Software Dependencies*

To give an extreme example of this, I once worked on an application which used Hazelcast<sup>14</sup> to cache log-in session tokens for a 3rd party datasource. But, the app is only used once every month, and session IDs can be obtained in milliseconds. So... why cache them? Although Hazelcast is an excellent choice for in-memory caching across multiple JVMs, it is a complex piece of software (after all, it does lots of stuff). By doing this, you have introduced extra dependency risk, cache invalidation risks, networking risks, synchronisation risks and so on, for actually no benefit at all... Unless, it's about CV Building.

Sometimes, the amount of complexity *goes up* when you use a dependency for *good reason*. For example, in Java, you can use Java Database Connectivity (JDBC) to interface with various types of database. Spring Framework<sup>15</sup> (a popular Java library) provides a thing called a `JDBCTemplate`. This actually makes your code *more* complex, and can prove very difficult to debug. However, it prevents some security issues, handles resource disposal and makes database access more efficient. None of those are essential to interfacing with the database, but not using them is Technical Debt that can bite you later on.

*Figure 8.7: Software Libraries Risk Tradeoff*

### 3. Software as a Service

Businesses opt for Software as a Service (SaaS) because:

- It vastly reduces the Complexity Risk they face in their organisations. e.g. managing the software or making changes to it.
- Payment is usually based on *usage*, mitigating Schedule Risk. e.g. Instead of having to pay for in-house software administrators, they can leave this function to the experts.
- Potentially, you outsource the Operational Risk to a third party. e.g. ensuring availability, making sure data is secure and so on.

<sup>14</sup><https://en.wikipedia.org/wiki/Hazelcast>

<sup>15</sup>[https://en.wikipedia.org/wiki/Spring\\_Framework](https://en.wikipedia.org/wiki/Spring_Framework)

SaaS is now a very convenient way to provide *commercial* software. Popular examples of SaaS might be SalesForce<sup>16</sup>, or GMail<sup>17</sup>. Both of which follow the commonly-used Freemium<sup>18</sup> model, where the basic service is provided free, but upgrading to a paid account gives extra benefits.

By providing the software on their own servers, the commercial organisation has a defence against *piracy*, as well as being able to control the Complexity Risk of the their environment (e.g. not having to support *every* version of the software that's ever been released).

Let's again recap the risks raised in some of the available literature:

Some take-aways:

- Clearly, Operational Risk is now a big concern. By depending on a third-party organisation you are tying yourself to its success or failure in a much bigger way than just by using a piece of open-source software. What happens to data security, both in the data centre and over the internet?
- With Feature Risk you now have to contend with the fact that the software will be upgraded *outside your control*, and you may have limited control over which features get added or changed.
- Boundary Risk is also a different proposition: you are tied to the software provider by *a contract*. If the service changes in the future, or isn't to your liking, you can't simply fork the code (like you could with an open source project).

## 8.4 A Matrix of Options

We've looked at just 3 different ways of providing a software dependency: SaaS, Libraries and code-your-own.

But these are not the only ways to do it, and there's clearly no one *right* way. Although here we have looked just at "Commercial SaaS" and "Free Open Source", in reality, these are just points in a two-dimensional space involving *Pricing* and *Hosting*.

Let's expand this view slightly and look at where different pieces of software sit on these axes:

---

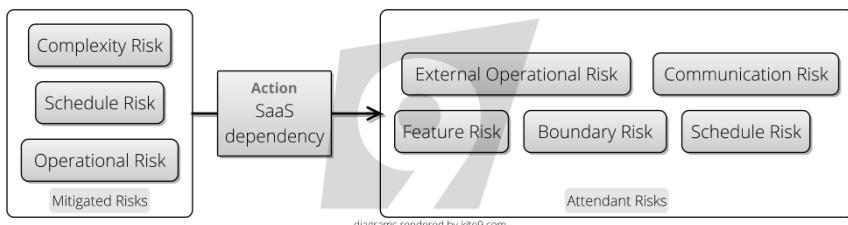

<sup>16</sup><https://en.wikipedia.org/wiki/Salesforce.com>

<sup>17</sup><https://en.wikipedia.org/wiki/Gmail>

<sup>18</sup><https://en.wikipedia.org/wiki/Freemium>

*Figure 8.10: Software Dependencies, Pricing, Delivery Matrix Risk Profiles*

- Where there is value in the Network Effect<sup>19</sup>, it's often a sign that the software will be free, or open source: programming languages and Linux are the obvious examples of this. Bugs are easier to find when there are lots of eyes looking, and learning the skill to use the software has less Boundary Risk if you know you'll be able to use it at any point in the future.
- At the other end of the spectrum, clients will happily pay for software if it clearly **reduces complexity**. Take Amazon Web Services (AWS)<sup>20</sup>. The essential trade here is that you substitute the complexity of hosting and maintaining various pieces of software, in exchange for monthly payments (Funding Risk for you). Since the AWS *interfaces* are specific to Amazon, there is significant Boundary Risk in choosing this option.
- In the middle there are lots of **substitute options** and therefore high competition. Because of this, prices are pushed towards zero, and therefore often advertising is used to monetarize the product. Angry Birds<sup>21</sup> is a classic example: initially, it had demo and paid versions, however Rovio<sup>22</sup> discovered there was much more money to be made through advertising than from the paid-for app<sup>23</sup>.

## Managing Risks

So far, we've considered only how the different approaches to Software Dependencies change the landscape of risks we face to mitigate some Feature Risk or other.

But with Software Dependencies we can construct dependency networks to give us all kinds of features and mitigate all kinds of risk. That is, *the features we are looking for are to mitigate some kind of risk*.

For example, I might start using WhatsApp<sup>24</sup> for example, because I want to be able to send my friends photos and text messages. However, it's likely that those same features are going to allow us to mitigate Communication Risk and Coordination Risk when we're next trying to meet up.

Let's look at some:

---

<sup>19</sup>[https://en.wikipedia.org/wiki/Network\\_effect](https://en.wikipedia.org/wiki/Network_effect)

<sup>20</sup>[https://en.wikipedia.org/wiki/Amazon\\_Web\\_Services](https://en.wikipedia.org/wiki/Amazon_Web_Services)

<sup>21</sup>[https://en.wikipedia.org/wiki/Angry\\_Birds](https://en.wikipedia.org/wiki/Angry_Birds)

<sup>22</sup>[https://en.wikipedia.org/wiki/Rovio\\_Entertainment](https://en.wikipedia.org/wiki/Rovio_Entertainment)

<sup>23</sup><https://www.deconstructoroffun.com/blog/2017/6/11/how-angry-birds-2-multiplied-quadrupled-revenue-in-a-year>

<sup>24</sup><https://en.wikipedia.org/wiki/WhatsApp>

Risk	Examples of Software Mitigating That Risk
Coordination Risk	Calendar tools, Bug Tracking, Distributed Databases
Map-And-Territory-Risk	The Internet, generally. Excel, Google, “Big Data”, Reporting tools
Schedule-Risk	Planning Software, Project Management Software
Communication-Risk	Email, Chat tools, CRM tools like SalesForce, Forums, Twitter, Protocols
Process-Risk	Reporting tools, online forms, process tracking tools
Agency-Risk	Auditing tools, transaction logs, Timesheet software, HR Software
Operational-Risk	Support tools like ZenDesk, Grafana, InfluxDB, Geneos
Feature-Risk	Every piece of software you use!

## 8.5 Back To Ergonomics

What's clear from this analysis is that software dependencies don't *conquer* any risk - the moves they make on the Risk Landscape are *subtle*. Whether or not you end up in a more favourable position risk-wise is going to depend heavily on the quality of the execution and the skill of the implementor.

In particular, *choosing* dependencies can be extremely difficult. As we discussed above, the usefulness of any tool depends on its fit for purpose, it's *ergonomics within a given context*. It's all too easy to pick a good tool for the wrong job:

“I suppose it is tempting, if the only tool you have is a hammer, to treat everything as if it were a nail.” - Abraham Maslow, *Toward a Psychology of Being*<sup>25</sup>

With software dependencies, we often have to live with the decisions we make for a long time. In my experience, given the Boundary Risks associated with getting this wrong, not enough time is spent really thinking about this in advance.

Let's take a closer look at this problem in the next chapter, Boundary Risk.

---

# Process Risk

Process Risk, as we will see, is the risk you take on whenever you embark on completing a *process*.

**“Process:** A process is a set of activities that interact to achieve a result.” - Process, *Wikipedia*<sup>1</sup>

In the software development world (and the business world generally) processes commonly involve *forms*: If you’re filling out a form (whether on paper or on a computer) then you’re involved in a process of some sort, whether an “Account Registration” process, “Loan Application” process or “Consumer Satisfaction Survey” process. But sometimes, they involve events occurring: a build process<sup>2</sup> might start after you commit some code, for example.

## 9.1 The Purpose Of Process

Process exists to mitigate other kinds of risk, and for this reason, we’ll be looking at them again in Part 3: Practices, where we’ll look at how you can design processes to mitigate risks on your own project.

Until we get there, let’s look at some examples of how process can mitigate other risks:

- Coordination Risk: You can often use process to help people coordinate. For example, a Production Line<sup>3</sup> is a process where work being done

---

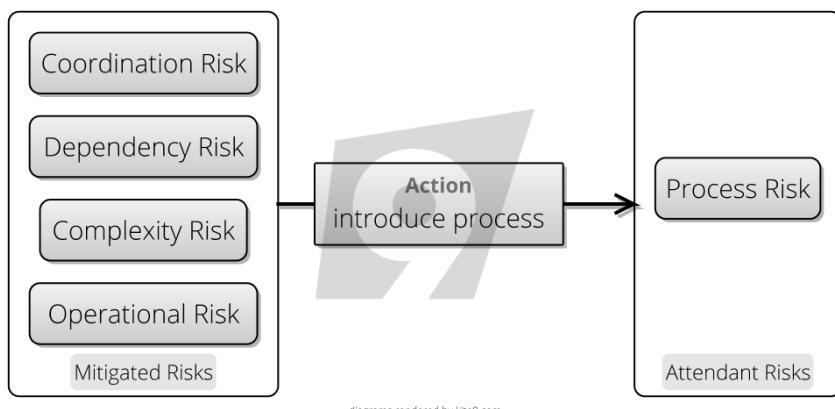

<sup>1</sup><https://en.wikipedia.org/wiki/Process>

<sup>2</sup>[https://en.wikipedia.org/wiki/Software\\_build](https://en.wikipedia.org/wiki/Software_build)

<sup>3</sup>[https://en.wikipedia.org/wiki/Production\\_line](https://en.wikipedia.org/wiki/Production_line)

by one person is pushed to the next person when it's done. A meeting booking process ensures that people will all attend a meeting together at the same place and time, and that a room is available for it.

- Dependency Risk: You can use processes to make dependencies explicit and mitigate dependency risk. For example, a process for hiring a car will make sure there is a car available at the time you need it. Alternatively, if we're processing a loan application, we might need evidence of income or bank statements. We can push this Dependency Risk onto the person asking for the loan, by making it part of the process and not accepting the application until this has been provided.
- Complexity Risk: Working *within a process* can reduce the amount of Complexity you have to deal with. We accept that processes are going to slow us down, but we appreciate the reduction in risk this brings. (They allow us to trade Complexity for Schedule risk). For example, setting up a server might be complex, but filling in a form to do the job might simplify things. Clearly, the complexity hasn't gone away, but it's hidden within the process. Process therefore can provide Abstraction. mcdonalds. tbd
- Operational Risk: Operational Risk encompasses the risk of people *not doing their job properly*. But, by having a process, (and asking, did this person follow the process?) you can draw a distinction between a process failure and a personnel failure. For example, making a loan to a money launderer *could* be a failure of the loan agent. But, if they followed the *process*, it's a failure of the Process itself.

*Figure 9.1: Introducing process can mitigate many risks for a team, but there are attendant process risks created.*

These are all examples of Risk Mitigation for the *owners* of the process. The

*consumers* of the process end up picking up most of the Process Risks. Let's see how this comes about.

## 9.2 Evolution Of Business Process

Before we get to examining what constitutes Process Risks, let's consider how processes *form*. Specifically, we're going to look at Business Process<sup>4</sup>:

**"Business Process or Business Method** is a collection of related, structured activities or tasks that in a specific sequence produces a service or product (serves a particular business goal) for a particular customer or customers." - Business Process, *Wikipedia*

Business Processes often arise in response to an unmet need within an organisation. And, as we said above, they are usually there to mitigate other risks. Let's look at an example lifecycle of how that can happen.

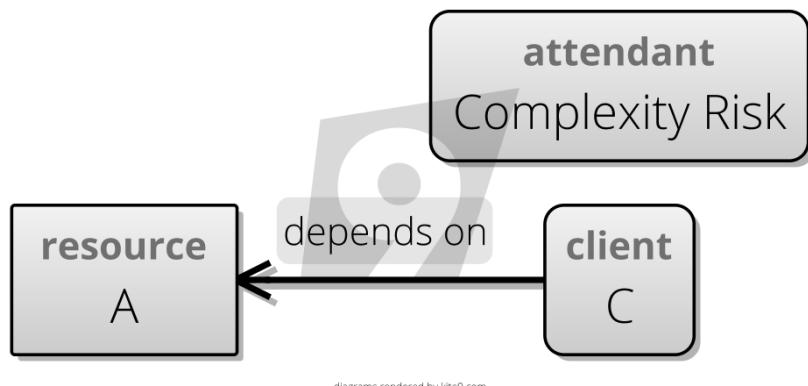

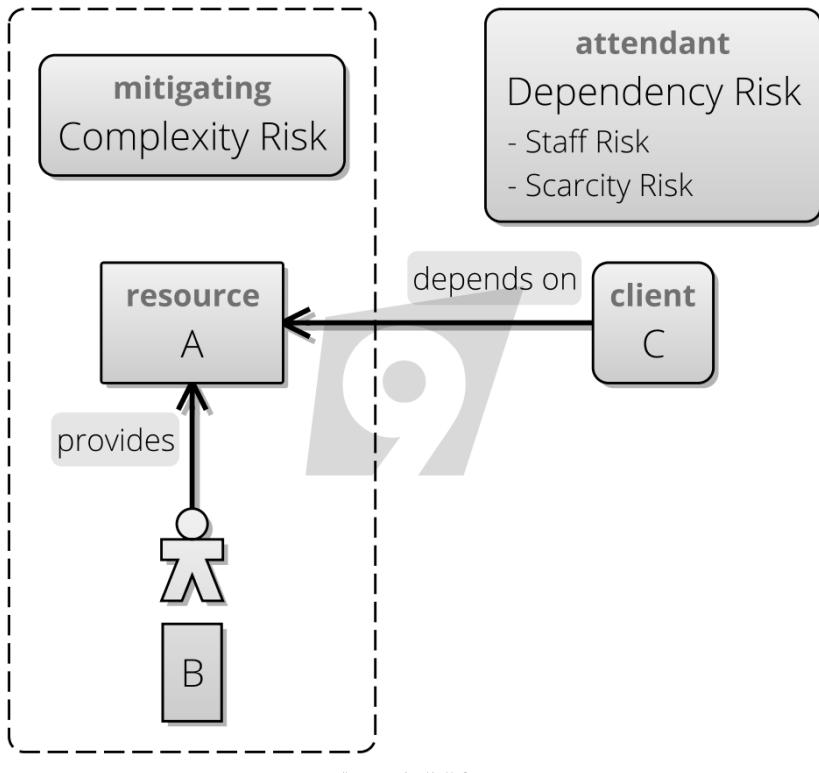

Figure 9.2: Step 0: Clients C need A to do their jobs

0. Let's say, there exists a group of people inside a company C, which need a certain something A in order to get their jobs done. It might be a producing a resource, or dealing with some source of complexity, or whatever.
  
1. Person B in a company starts producing A as a service to others. This is really useful! It makes the the lives of clients in C much easier as they

<sup>4</sup>[https://en.wikipedia.org/wiki/Business\\_process](https://en.wikipedia.org/wiki/Business_process)

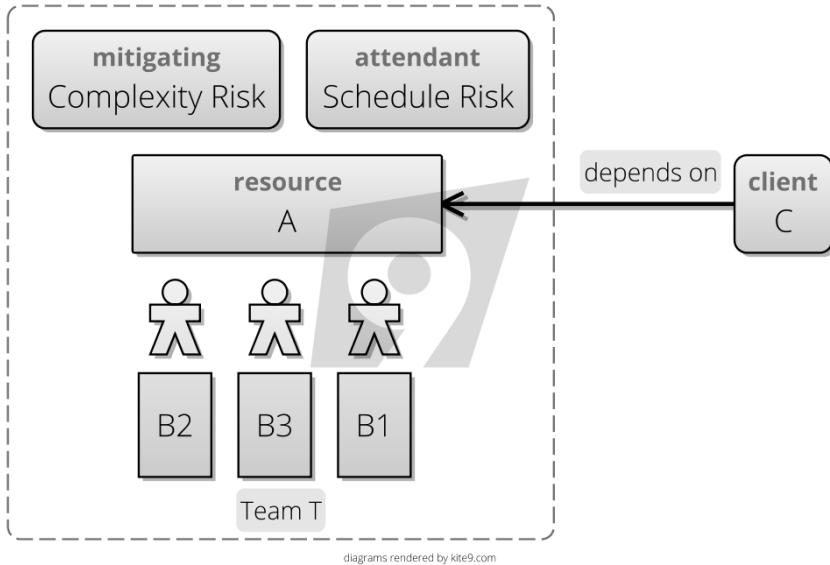

diagrams rendered by kite9.com

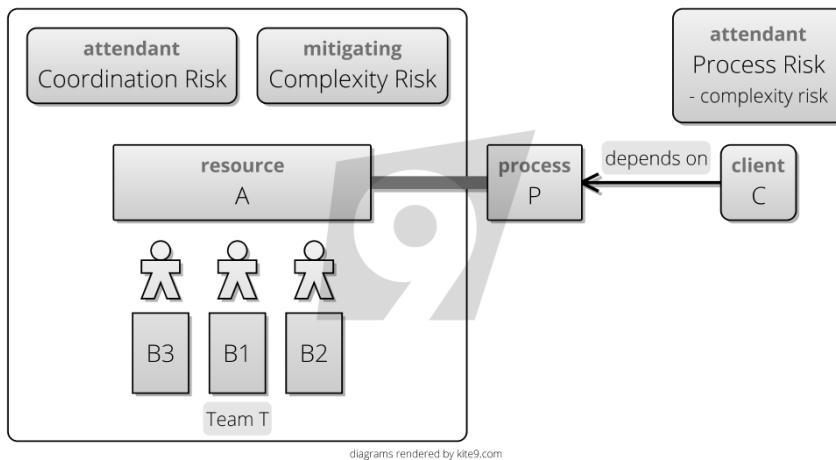

*Figure 9.3: Step 1: Person B doing A for company C*

have an easier path to A than before. B gets busy keeping C happy. No one cares. But then, B goes on holiday. A doesn't get done, and people now care: the Dependency Risk is suddenly apparent.

2. Either, B co-opts other people to help, gets given a team (T), or someone else forms a team T containing B to get the job done “properly”.
  - T is responsible for doing A, but it needs to supply the company with A reliably and responsibly, otherwise there will be trouble, so they try and please all of their clients as far as possible.
  - This is a good deal for their clients within C, but because there is a lot of variation in what the clients ask for, T end up absorbing a lot of Complexity Risk and are overworked.
  - This is attendant Schedule Risk: They either need to streamline what they are doing, or get a larger budget, because all this extra Complexity impacts their ability to reliably deliver A.

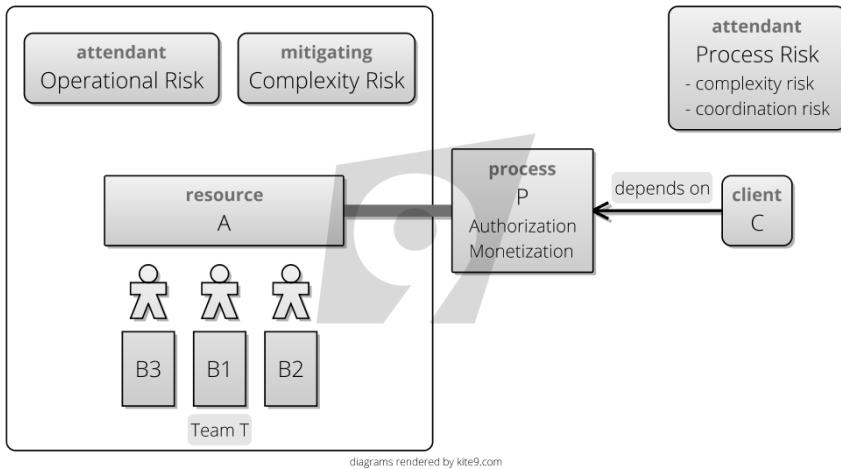

*Figure 9.4: Step 2: Team T is created to do A for Company C*

*Figure 9.5: Team T protects itself from complexity with a process, P*

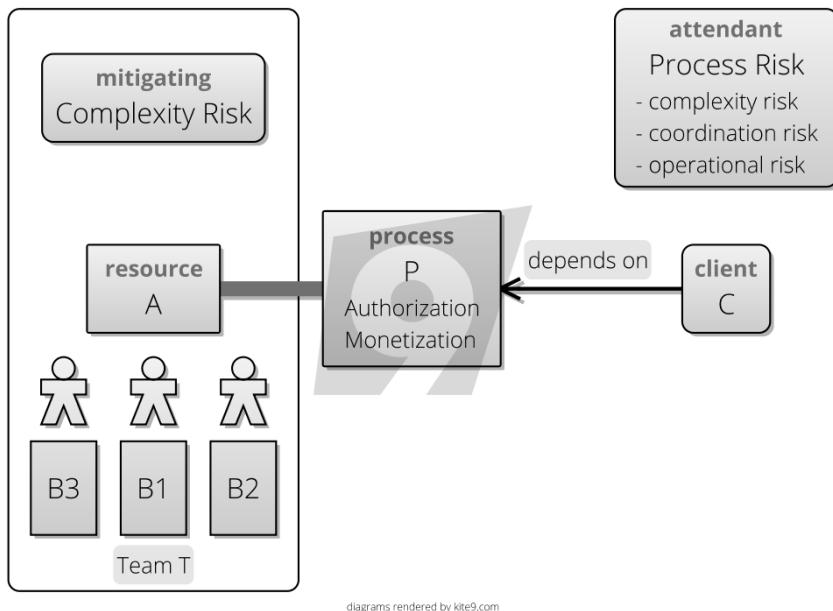

3. T organises bureaucratically, so that there is a controlled process (P) by which A can be accessed. Like a cell, they have arranged a protective barrier around themselves, the strength of which depends on the power conferred to them by control of A.
  - P probably involves filling in a form (or following some other Protocol).

- T can now deal with requests on a first-come-first-served basis and deal with them all in the same way: Complexity Risks are now the problem of the form-filler in C.
- T has mitigated Schedule Risk issues by drawing a line around the amount of Complexity Risk they are willing to take on.
- C now has Process Risk: will their requirements for A be met by T? They have to submit to the process to find out...

**Figure 9.6: Team T protects itself from Coordination issues with signoffs or other barriers**

4. But it's hard to make sure the right clients get access to A at the right times, and it's necessary to synchronize access across company C. (A Coordination Risk issue.)
  - T reacts and sets up sign-off, authorization or monetary barriers around A, moving the Coordination Risk issue out of their team.
  - But, for C, this *again* increases the Process Risk involved in using A.
5. But, there are abuses of A: people either misuse it, or use it too much. (These are Operational Risks.)
  - T reacts by *increasing* the amount of *process* to use A, mitigating Operational Risk within their team, but...
  - This corresponds to greater Process Risk for clients in company C.

diagrams rendered by kite9.com

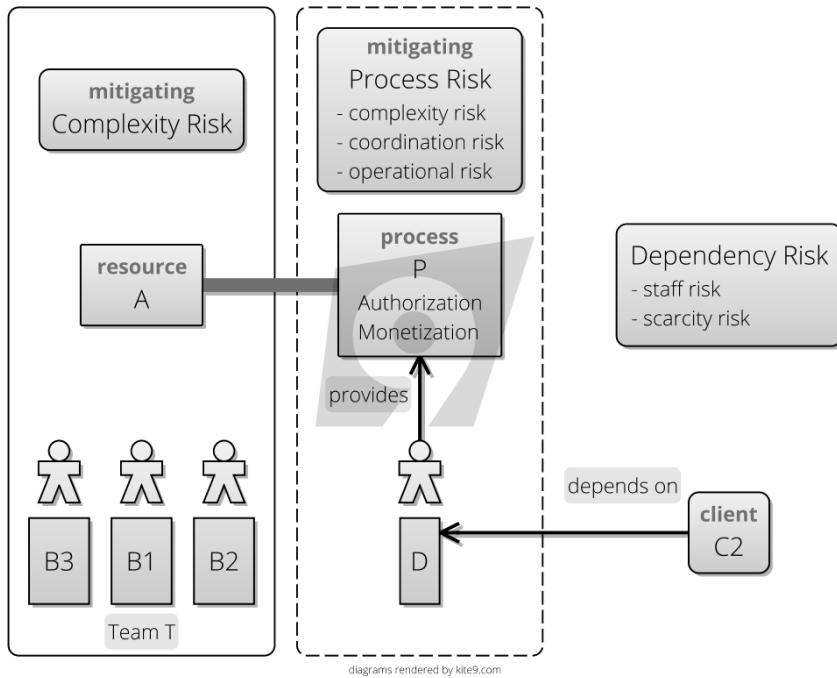

**Figure 9.7: Team T increases bureaucratic load, and pushes Process Risk onto C**

6. Person D, who has experience working with team T acts as a middleman for customers requiring some variant of A for a subset of C. They are able to help navigate the bureaucratic process (handle with Process Risk). The cycle potentially starts again: will D end up becoming a new team, with a new process?

In this example, you can see how the organisation evolves to mitigate risk around the use (and misuse) of A: First, Complexity Risk, then Coordination Risk, then Dependency Risk and finally, the Process Risk was created to mitigate everything else. This is an example of *Process following Strategy*:

In this conception, you can see how the structure of an organisation (the teams and processes within it, the hierarchy of control) will 'evolve' from the resources of the organisation and the strategy it pursues. Processes evolve to meet the needs of the organisation." - Mintzberg, *Strategy Safari*<sup>5</sup>

<sup>5</sup><http://www.mintzberg.org/books/strategy-safari>

*Figure 9.8: Person D acts as a middleman for customers needing some variant of A*

### 9.3 An Example - Release Process

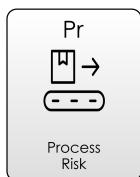

For many years I have worked in the Finance Industry, and it's given me time to observe how, across an entire industry, process can evolve, both in response to regulatory pressure but also because of organisational maturity, and mitigating risks:

1. Initially, I could release software by logging onto the production accounts with a password that everyone knew, and deploy software or change data in the database.
2. The first issue with this is bad actors: How could you know that the numbers weren't being altered in the databases? Production auditing came in so that at least you could tell *who was changing what*, in order to point the blame later.
3. But, there was still plenty of scope for deliberate or accidental damage. I personally managed to wipe production data on one occasion by mistaking it for a development environment. Eventually, passwords were taken out of the hands of developers and you needed approval to "break glass" to get onto production.

4. Change Requests were introduced. This is another approval process which asks you to describe what you want to change in production, and why you want to change it. In most places, this was quite an onerous process, so the unintended consequence was that release cadence was reduced.
5. The change request software is generally awful, making the job of raising change requests tedious and time-consuming. Therefore, developers would *automate* the processes for release, sometimes including the process to write the change request. This allowed them to improve release cadence, at the expense of owning more code.
6. Auditors didn't like the fact that this automation existed, because effectively, that meant that developers could get access to production with the press of a button, effectively taking you back to step 1. So auditing of Change Requests had to happen.

... and so on.

## 9.4 Process Risks

- Risks due to the fact that when dealing with a dependency, we have to follow a particular protocol of communication, which may not work out the way we want.

*Figure 9.9: Process Risk*

**Process Risk**, then, is a type of Dependency Risk, where you are relying on a process. In a way, it's no different from any other kind of Dependency Risk. But Process Risk manifests itself in fairly predictable ways:

- Reliability Risk: If *people* are part of the process, there's the chance that they forget to follow the process itself, and miss steps or forget your request completely. The reliability is related to the amount of Complexity Risk the process is covering.
- Invisibility Risk: Usually, processes (like other dependencies) trade Complexity Risk for visibility: it's often not possible to see how far along a process is to completion. Sometimes, you can do this to an

extent. For example, when I send a package for delivery, I can see roughly how far it's got on the tracking website. But, this is still less-than-complete information, and is a representation of reality.

- Fit Risk: You have to be careful to match the process to the outcome you want. Sometimes, it's easy to waste time on the wrong process.
- Dead-End Risk: Even if you have the right process, initiating a process has no guarantee that your efforts won't be wasted and you'll be back where you started from. The chances of this happening increase as you get further from the standard use-case for the process, and the sunk cost increases with the length of time the process takes to report back.
- Agency Risk: Due to Parkinson's Law, see below.
- Operational Risk: Where processes fail, this is often called Operational Risk, which we'll address further in its own chapter.
- Credit Risk: Where you pay for something to be done, but then end up without the outcome you want. Let's look at that in more detail.

## Processes And Invisibility Risk

Processes tend to work well for the common cases, because *practice makes perfect*. but they are really tested when unusual situations occur. Expanding processes to deal with edge-cases incurs Complexity Risk, so often it's better to try and have clear boundaries of what is "in" and "out" of the process' domain.

Sometimes, processes are *not* used commonly. How can we rely on them anyway? Usually, the answer is to build in extra feedback loops anyway:

- Testing that backups work, even when no backup is needed.
- Running through a disaster recovery scenario at the weekend.
- Increasing the release cadence, so that we practice the release process more.

The feedback loops allow us to perform Retrospectives and Reviews to improve our processes.

## Bureaucracy Risk

Where we've talked about process evolution above, the actors involved have been acting in good faith: they are working to mitigate risk in the organisation. The Process Risk that accretes along the way is an *unintended consequence*: There is no guarantee that the process that arises will be humane and intuitive. Many organisational processes end up being baroque or Kafkaesque,

- Risk that a particular dependency devolves into a self-serving bureaucracy due to some kind of agency issue.

**Figure 9.10: Bureaucracy Risk**

forcing unintuitive behaviour on their users. This is partly because process design is *hard*, and it's difficult to anticipate all the various ways a process will be used ahead-of-time. So, some of Bureaucracy Risk is due to Complexity.

But Parkinson's Law<sup>6</sup> takes this one step further: the human actors shaping the organisation will abuse their positions of power in order to further their own careers (this is Agency Risk, which we will come to in a future chapter):

"Parkinson's law is the adage that "work expands so as to fill the time available for its completion". It is sometimes applied to the growth of bureaucracy in an organization... He explains this growth by two forces: (1) 'An official wants to multiply subordinates, not rivals' and (2) 'Officials make work for each other.'" - Parkinson's Law, *Wikipedia*

This implies that there is a tendency for organisations to end up with *needless levels of Bureaucratic Risk*.

## Credit Risk

- A specific version of reliability risk where the risk is due to money owed by one or other party.

**Figure 9.11: Credit Risk**

---

<sup>6</sup>[https://en.wikipedia.org/wiki/Parkinson%27s\\_law](https://en.wikipedia.org/wiki/Parkinson%27s_law)

Where the process you depend on is being run by a third-party organisation, (or that party depends on you) you are looking at Credit Risk (also known as Counterparty Risk):

"A credit risk is the risk of default on a debt that may arise from a borrower failing to make required payments... For example... A business or consumer does not pay a trade invoice when due [or] A business does not pay an employee's earned wages when due" - Credit Risk, *Wikipedia*

Money is *changing hands* between you and the supplier of the process, and often, the money doesn't transfer *at the same time* as the process is performed. Let's look at an example: Instead of hosting my website on a server in my office, I could choose to host my software project with an online provider. I am trading Complexity Risk for Credit Risk, because now, I have to care that the supplier is solvent.

There's a couple of ways this could go wrong: They may *take my payment*, but then turn off my account. Or, they could go bankrupt, and leave me with the costs of moving to another provider (this is also Dead-End Risk).

Mechanisms like insurance<sup>7</sup>, contracts<sup>8</sup> and guarantees<sup>9</sup> help mitigate this risk at the cost of complexity and expense.

## Sign-Offs

Often, Processes will include sign-off steps. The Sign-Off is an interesting mechanism: - By signing off on something for the business, people are usually in some part staking their reputation on something being right. - Therefore, you would expect that sign-off involves a lot of Agency Risk: people don't want to expose themselves in career-limiting ways. - Therefore, the bigger the risk they are being asked to swallow, the more cumbersome and protracted the sign off process.

Often, Sign Offs boil down to a balance of risk for the signer: on the one hand, *personal, career risk* from signing off, on the other, the risk of upsetting the rest of the staff waiting for the sign-off, and the Dead End Risk of all the effort gone into getting the sign off if they don't.

This is a nasty situation, but there are a couple of ways to de-risk this: - break Sign Offs down into bite-size chunks of risk that are acceptable to those doing

---

<sup>7</sup>[https://en.wikipedia.org/wiki/Insurance\\_policy](https://en.wikipedia.org/wiki/Insurance_policy)

<sup>8</sup><https://en.wikipedia.org/wiki/Contract>

<sup>9</sup><https://en.wikipedia.org/wiki/Guarantee>

the sign-off. - Agree far-in-advance the sign-off criteria. As discussed in Risk Theory, people have a habit of heavily discounting future risk, and it's much easier to get agreement on the *criteria* than it is to get the sign-off.

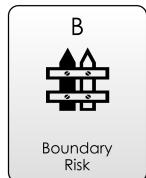

## **Software Processes**

tbd

tbd. processes as a response to legal environment.

# Boundary Risk

- Risks due to the choices we make around dependencies, and the limitations they place on our ability to change.

*Figure 10.1: Boundary Risk*

In the previous few chapters on Dependency Risk we've touched on Boundary Risk several times, but now it's time to tackle it head-on and discuss this important type of risk.

In terms of the Risk Landscape, Boundary Risk is exactly as it says: a *boundary*, *wall* or other kind of obstacle in your way to making a move you want to make. This changes the nature of the Risk Landscape, and introduces a maze-like component to it. It also means that we have to make *decisions* about which way to go, knowing that our future paths are constrained by the decisions we make.

And, as we discussed in Complexity Risk, there is always the chance we end up at a Dead End, and we've done work that we need to throw away. In this case, we'll have to head back and make a different decision.

- The risk that a particular approach to a change will fail.  
Caused by the fact that at some level, our internal  
models are not a complete reflection of reality.

Figure 10.2: Dead-End Risk

## 10.1 Emergence Through Choice

Boundary Risk is an emergent risk, which exists at the intersection of Complexity Risk, Dependency Risk and Communication Risk. Because of that, it's going to take a bit of time to pick it apart and understand it, so we're going to build up to this in stages.

Let's start with an obvious example: Musical Instruments. Let's say you want to learn to play some music. There are a *multitude* of options available to you, and you might choose an *uncommon* instrument like a Balalaika<sup>1</sup> or a Theremin<sup>2</sup>, or you might choose a *common* one like a piano or guitar. In any case, once you start learning this instrument, you have picked up the three risks above:

- Dependency Risk You have a *physical* Dependency on it in order to play music, so get to the music shop and buy one.
- Communication Risk: You have to *communicate* with the instrument in order to get it to make the sounds you want. And you have Learning Curve Risk in order to be able to do that.
- Complexity Risk: As a *music playing system*, you now have an extra component (the instrument), with all the attendant complexity of looking after that instrument, tuning it, and so on.

Those risks are true for *any* instrument you choose. However, if you choose the *uncommon* instrument like the Balalaika, you have *worse* Boundary Risk, because the *ecosystem* for the balalaika is smaller. It might be hard to find a tutor, or a band needing a balalaika. You're unlikely to find one in a friend's house (compared to the piano, say).

---

<sup>1</sup><https://en.wikipedia.org/wiki/Balalaika>

<sup>2</sup><https://en.wikipedia.org/wiki/Theremin>

Even choosing the Piano has Boundary Risk. By spending your time learning to play the piano, you're mitigating Communication Risk issues, but *mostly*, your skills won't be transferrable to playing the guitar. Your decision to choose one instrument over another cements the Boundary Risk: you're following a path on the Risk Landscape and changing to a different path is *expensive*.

Also, it stands to reason that making *any* choice is better than making *no* choice, because you can't try and learn *all* the instruments. Doing that, you'd make no meaningful progress on any of them.

## 10.2 Boundary Risk For Software Dependencies

Let's look at a software example now.

As discussed in Software Dependency Risk, if we are going to use a software tool as a dependency, we have to accept the complexity of its Interface, and learn the protocol of that interface. If you want to work with it, you have to use its protocol, it won't come to you.

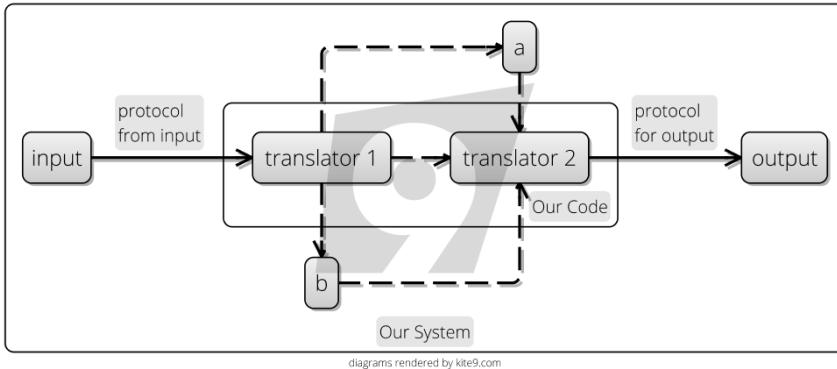

Let's take a look at a hypothetical system structure, in the accompanying diagram. In this design, we have are transforming data from the input to the output. But how should we do it?

- We could go via a, using the Protocols of a, and having a dependency on a.
- We could go via b, using the Protocols of b, and having a dependency on b.
- We could choose the middle route, and avoid the dependency, but potentially pick up lots more Complexity Risk and Schedule Risk.

This is a basic **Translation** job from input to output. Since we are talking about **Translation**, we are clearly talking about Communication Risk again: our task in **Integrating** all of these components is *to get them to talk to each other*.

From a Cyclomatic Complexity point of view, this is a very simple structure, with low Complexity. But the choice of approach presents us with Boundary Risk, because we don't know that we'll be able to make them *talk to each other* properly:

- Maybe a outputs dates in a strange calendar format that we won't understand.

*Figure 10.3: Our System receives data from the **input**, translates it and sends it to the **output**. But which dependency should we use for the translation, if any?*

- Maybe b works on some streaming API basis, that is incompatible with the input protocol.
- Maybe a runs on Windows, whereas our code runs on Linux.

... and so on.

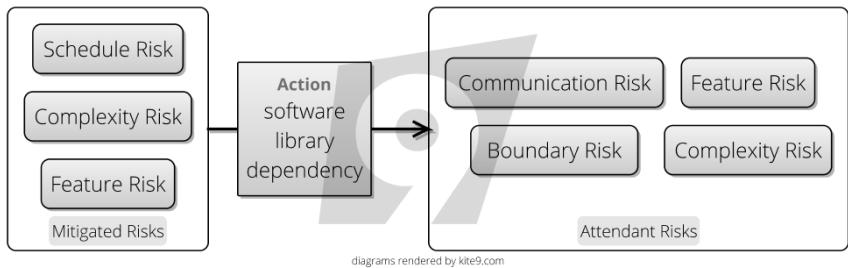

### 10.3 Boundary Risk Pinned Down

Wherever we integrate dependencies with complex Protocols, we potentially have Boundary Risk. The more complex the systems being integrated, the higher the risk. When we choose software tools or libraries to help us build our systems, we are trading Complexity Risk for Boundary Risk. It is:

- The *sunk cost* of the Learning Curve we've overcome to integrate the dependency, when it fails to live up to expectations.
- The likelihood of, and costs of changing in the future.
- The rarity of alternatives (or, conversely, the risk of Lock In).

As we saw in Software Dependency Risk, Boundary Risk is a big factor in choosing libraries and services. However, it can apply to any kind of dependency:

- If you're depending on a Process or Organisation, they might change their products or quality, making the effort you put into the relationship worthless.

*Figure 10.4: The tradeoff for using a library*

- If you're depending on Staff, they might leave, meaning your efforts on training them don't pay back as well as you hoped.
- If you're depending on an Event occurring at a particular time, you might have a lot of work to reorganise your life if it changes time or place.

## 10.4 Avoiding Boundary Risk Now...

Because of Boundary Risk's relationship to Learning Curve Risk, we can avoid accreting it by choose the *simplest* and *fewest* dependencies for any job. Let's look at some examples:

- `mkdirp` is an npm<sup>3</sup> module defining a single function. This function takes a single string parameter and recursively creating directories. Because the protocol is so simple, there is almost no Boundary Risk.
- Using a database with a JDBC driver comes with *some* Boundary Risk: but the boundary is specified by a standard. Although the standard doesn't cover every aspect of the behaviour of the database, it does minimize risk, because if you are familiar with one JDBC driver, you'll be familiar with them all, and swapping one for another is relatively easy.
- Using a framework like Spring<sup>4</sup>, Redux<sup>5</sup> or Angular<sup>6</sup> comes with higher Boundary Risk: you are expected to yield to the framework's way of behaving throughout your application. You cannot separate the concern easily, and swapping out the framework for another is likely to leave you with a whole new set of assumptions and interfaces to deal with.

---

<sup>3</sup><https://www.npmjs.com>

<sup>4</sup><https://spring.io>

<sup>5</sup><https://redux.js.org>

<sup>6</sup><https://angularjs.org>

## 10.5 ... And In The Future

Unless your project *ends*, you can never be completely sure that Boundary Risk *isn't* going to stop you making a move you want. For example:

- `mkdirp` might not work on a new device's Operating System, forcing you to swap it out.
- You might discover that the database you chose satisfied all the features you needed at the start of the project, but came up short when the requirements changed later on.
- The front-end framework you chose might go out-of-fashion, and it might be hard to find developers interested in working on the project because of it.

This third point is perhaps the most interesting aspect of Boundary Risk: how can we ensure that the decisions we make now are future-proof? In order to investigate this further, let's look at three things: Plugins, Ecosystems and Evolution (again).

## 10.6 Plugins, Ecosystems and Evolution

On the face of it, WordPress<sup>7</sup> and Drupal<sup>8</sup> *should* be very similar:

- They are both Content Management Systems<sup>9</sup>
- They both use a LAMP (Linux, Apache, MySQL, PHP) Stack<sup>10</sup>
- They were both started around the same time (2001 for Drupal, 2003 for WordPress)
- They are both Open-Source, and have a wide variety of Plugins<sup>11</sup>. That is, ways for other programmers to extend the functionality in new directions.

In practice, they are very different. This could be put down to different *design goals*: it seems that WordPress was focused much more on usability, and an easy learning curve, whereas Drupal supported plugins for building things with complex data formats. It could also be down to the *design decisions*: although they both support Plugins, they do it in very different ways.

---

<sup>7</sup><https://en.wikipedia.org/wiki/WordPress>

<sup>8</sup><https://en.wikipedia.org/wiki/Drupal>

<sup>9</sup>[https://en.wikipedia.org/wiki/Content\\_management\\_system](https://en.wikipedia.org/wiki/Content_management_system)

<sup>10</sup>[https://en.wikipedia.org/wiki/LAMP\\_\(software\\_bundle\)](https://en.wikipedia.org/wiki/LAMP_(software_bundle))

<sup>11</sup>[https://en.wikipedia.org/wiki/Plug-in\\_\(computing\)](https://en.wikipedia.org/wiki/Plug-in_(computing))

(Side note: I wasn't short of go-to examples for this. I could have picked on Team City<sup>12</sup> and Jenkins<sup>13</sup> here (Continuous Integration<sup>14</sup> tools), or Maven<sup>15</sup> and Gradle<sup>16</sup> (build tools). All of these support plugins), and the *choice* of plugins is dependent on which I've chosen, despite the fact that the platforms are solving pretty much the same problems. )

## Ecosystems and Systems

The quality, and choice of plugins for a given platform, along with factors such as community and online documentation is often called its ecosystem<sup>17</sup>:

"as a set of businesses functioning as a unit and interacting with a shared market for software and services, together with relationships among them" - Software Ecosystem, *Wikipedia*

You can think of the ecosystem as being like the footprint of a town or a city, consisting of the buildings, transport network and the people that live there. Within the city, and because of the transport network and the amenities available, it's easy to make rapid, useful moves on the Risk Landscape. In a software ecosystem it's the same: the ecosystem has gathered together to provide a way to mitigate various different Feature Risks in a common way.

tbd: talk about complexity within the boundary. (increased convenience?)

Ecosystem size is one key determinant of Boundary Risk: a *large* ecosystem has a large boundary circumference. Boundary Risk is lower because your moves on the Risk Landscape are unlikely to collide with it. The boundary *got large* because other developers before you hit the boundary and did the work building the software equivalents of bridges and roads and pushing it back so that the boundary didn't get in their way.

In a small ecosystem, you are much more likely to come into contact with the edges of the boundary. You will have to be the developer that pushes back the frontier and builds the roads for the others. This is hard work.

## Evolution

In the real world, there is a tendency for *big cities to get bigger*. The more people that live there, the more services they provide, and therefore, the

---

<sup>12</sup><https://en.wikipedia.org/wiki/TeamCity>

<sup>13</sup>[https://en.wikipedia.org/wiki/Jenkins\\_\(software\)](https://en.wikipedia.org/wiki/Jenkins_(software))

<sup>14</sup>[https://en.wikipedia.org/wiki/Continuous\\_integration](https://en.wikipedia.org/wiki/Continuous_integration)

<sup>15</sup>[https://en.wikipedia.org/wiki/Apache\\_Maven](https://en.wikipedia.org/wiki/Apache_Maven)

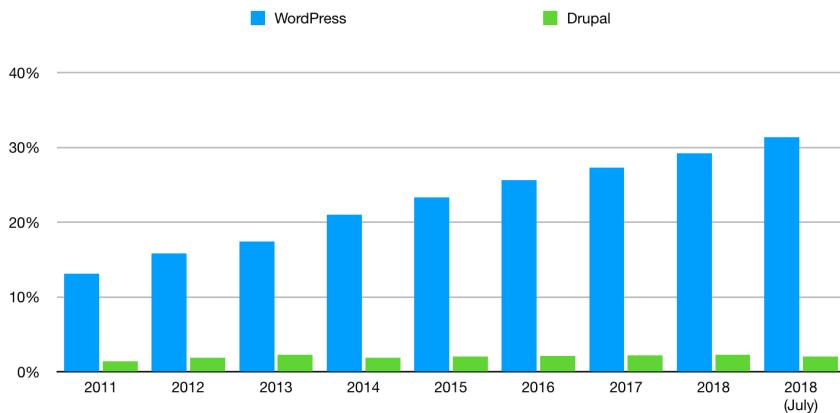

<sup>16</sup><https://en.wikipedia.org/wiki/Gradle>

<sup>17</sup>[https://en.wikipedia.org/wiki/Software\\_ecosystem](https://en.wikipedia.org/wiki/Software_ecosystem)

more immigrants they attract. And, it's the same in the software world. In both cases, this is due to the Network Effect:

"A network effect (also called network externality or demand-side economies of scale) is the positive effect described in economics and business that an additional user of a good or service has on the value of that product to others. When a network effect is present, the value of a product or service increases according to the number of others using it." - Network Effect, *Wikipedia*

You can see the same effect in the adoption rates of WordPress and Drupal, shown in the chart below. Note: this is over *all sites on the internet*, so Drupal accounts for hundreds of thousands of sites. In 2018, WordPress is approximately 32% of all websites. For Drupal it's 2%.

*Figure 10.5: Wordpress vs Drupal adoption over 8 years, according to w3techs.com<sup>18</sup>*

Did WordPress gain this march because it was better than Drupal? That's arguable. That it's this way round could be *entirely accidental*, and a result of Network Effect.

And maybe, they aren't comparable: Given the same problems, the people in each ecosystem have approached them and solved them in different ways. And, this has impacted the 'shape' of the abstractions, and the protocols you use in each. Complexity *emerges*, and the ecosystem gets more complex and opinionated, much like the way in which the network of a city will evolve over time in an unpredictable way.

But, by now, if they *are* to be compared side-by-side, WordPress *should be better* due to the sheer number of people in this ecosystem who are...

- Creating web sites.
- Using those sites.
- Submitting bug requests.
- Fixing bugs.
- Writing documentation.
- Building plugins.
- Creating features.
- Improving the core platform.

But, there are two further factors to consider...

## 1. The Peter Principle

When a tool or platform is popular, it is under pressure to increase in complexity. This is because people are attracted to something useful, and want to extend it to new purposes. This is known as *The Peter Principle*:

“The Peter principle is a concept in management developed by Laurence J. Peter, which observes that people in a hierarchy tend to rise to their ‘level of incompetence’.” - The Peter Principle, Wikipedia<sup>19</sup>

Although designed for *people*, it can just as easily be applied to any other dependency you can think of. Let’s look at Java<sup>20</sup> as an example of this.

Java is a very popular platform. Let’s look at how the number of public classes (a good proxy for the boundary) has increased with each release:

Why does this happen?

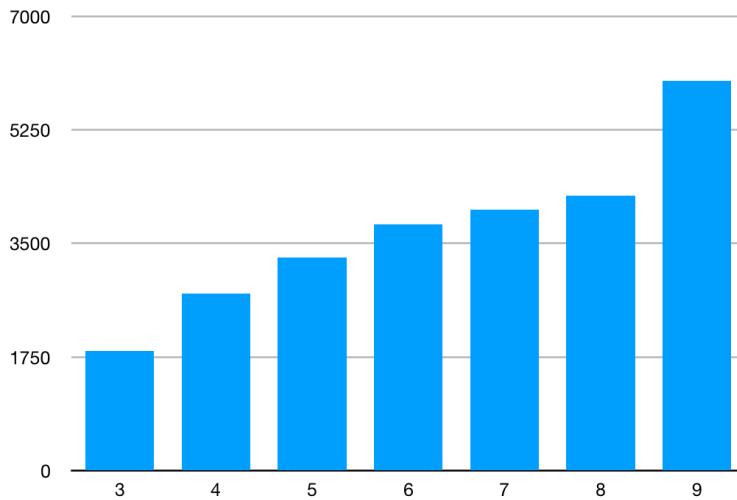

- More and more people are using Java for more and more things. It’s popularity begets more popularity.
- Human needs are *fractal* in complexity. You can always find ways to make a dependency *better* (For some meaning of better).
- There is Feature Drift Risk: our requirements evolve with time. Android Apps<sup>21</sup> weren’t even a thing when Java 3 came out, for example, yet they are all written in Java now, and Java has had to keep up.

---

<sup>19</sup>[https://en.wikipedia.org/wiki/Peter\\_principle](https://en.wikipedia.org/wiki/Peter_principle)

<sup>20</sup>[https://en.wikipedia.org/wiki/Java\\_\(software\\_platform\)](https://en.wikipedia.org/wiki/Java_(software_platform))

<sup>21</sup>[https://en.wikipedia.org/wiki/Android\\_software\\_development](https://en.wikipedia.org/wiki/Android_software_development)

*Figure 10.6: Java Public Classes By Version (3-9)*

## 2. Backward Compatibility

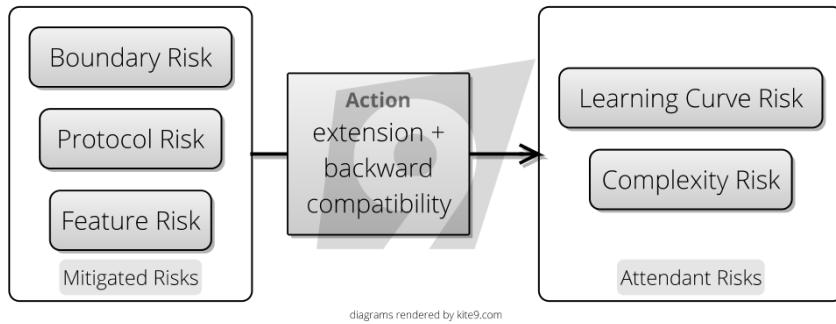

As we saw in Software Dependency Risk, The art of good design is to afford the greatest increase in functionality with the smallest increase in complexity possible, and this usually means Refactoring. But, this is at odds with Backward Compatibility.

Each new version has a greater functional scope than the one before (pushing back Boundary Risk), making the platform more attractive to build solutions in. But this increases the Complexity Risk as there is more functionality to deal with.

### Focus vs Overreach

You can see in the diagram the Peter Principle at play: as more responsibility is given to a dependency, the more complex it gets, and the greater the learning curve to work with it. Large ecosystems like Java react to Learning Curve Risk by having copious amounts of literature to read or buy to help, but it is still off-putting.

Because Complexity is Mass, large ecosystems can't respond quickly to Feature Drift. This means that when the world changes, *new* systems will come along to plug the gaps.

diagrams rendered by kite9.com

**Figure 10.7: The Peter Principle: Backward Compatibility + Extension leads to complexity and learning curve risk**

This implies a trade-off: - Sometimes it's better to accept the Boundary Risk innate in a smaller system than try to work within the bigger, more complex system.

example:

In the late 80's and 90's there was a massive push towards *building functionality in the database*. Relational Database Management Systems (RDBMSs) were all-in-one solutions, expensive platforms that you purchased and built *everything* inside. However, this dream didn't last:

why? (need some research here).

This tbd

tbd. diagram here.

## 10.7 Beating Boundary Risk With Standards

Sometimes, technology comes along that allows us to cross boundaries, like a *bridge* or a *road*. This has the effect of making it easy to go from one self-contained ecosystem to another. Going back to WordPress, a simple example might be the Analytics Dashboard which provides Google Analytics<sup>22</sup> functionality inside WordPress.

I find, a lot of code I write is of this nature: trying to write the *glue code* to join together two different *ecosystems*.

Standards allow us to achieve the same thing, in one of two ways:

---

<sup>22</sup>[https://en.wikipedia.org/wiki/Google\\_Marketing\\_Platform](https://en.wikipedia.org/wiki/Google_Marketing_Platform)

- **Mode 1: Abstract over the ecosystems.** Provide a *standard* protocol (a *lingua franca*) which can be converted down into the protocol of any of a number of competing ecosystems.
- **Mode 2: Force adoption.** All of the ecosystems start using the standard for fear of being left out in the cold. Sometimes, a standards body is involved, but other times a “de facto” standard emerges that everyone adopts.

Let's look at some examples:

- ASCII<sup>23</sup>: fixed the different-character-sets boundary risk by being a standard that others could adopt. Before everyone agreed on ASCII, copying data from one computer system to another was a massive pain, and would involve some kind of translation. Unicode<sup>24</sup> continues this work. (**Mode 1**)
- C<sup>25</sup>: The C programming language provided a way to get the same programs compiled against different CPU instruction sets, therefore providing some *portability* to code. The problem was, each different operating system would still have its own libraries, and so to support multiple operating systems, you'd have to write code against multiple different libraries. (**Mode 2**)
- Java<sup>26</sup> took what C did and went one step further, providing interoperability at the library level. Java code could run anywhere where Java was installed. (**Mode 2**)
- Internet Protocol: As we saw in Communication Risk, the Internet Protocol (IP) is the *lingua franca* of the modern internet. However, at one period of time, there were many competing standards. and IP was the ecosystem that “won”, and was subsequently standardized by the IETF<sup>27</sup>. (**Mode 1**)

## 10.8 Complex Boundaries

As shown in the above diagram, mitigating Boundary Risk involves taking on complexity. The more Protocol Complexity there is to bridge the two ecosystems, the more Complex the bridge will necessarily be.

---

<sup>23</sup><https://en.wikipedia.org/wiki/ASCII>

<sup>24</sup><https://en.wikipedia.org/wiki/Unicode>

<sup>25</sup>[https://en.wikipedia.org/wiki/C\\_\(programming\\_language\)](https://en.wikipedia.org/wiki/C_(programming_language))

<sup>26</sup>[https://en.wikipedia.org/wiki/Java\\_\(programming\\_language\)](https://en.wikipedia.org/wiki/Java_(programming_language))

<sup>27</sup>[https://en.wikipedia.org/wiki/Internet\\_Engineering\\_Task\\_Force](https://en.wikipedia.org/wiki/Internet_Engineering_Task_Force)

Protocol Risk From A	Protocol Risk From B	Resulting Bridge Complexity	Example
Low	Low	Simple	Changing from one date format to another.
High	Low	Moderate	Status Dashboard, tbd
High	High	Complex	Object-Relational Mapping (ORM) Tools, (see below)
High + Evolving	Low	Moderate, Versioned	Simple Phone App, e.g. note-taker or calculator
Evolving	High	Complex	Modern browser (see below)
Evolving	Evolving	Very Complex	Google Search, Scala (see below)

From examining the [Protocol Risk][br1] at each end of the bridge you are creating, you can get a rough idea of how complex the endeavour will be:

- If it's low-risk at both ends, you're probably going to be able to knock it out easily. Like translating a date, or converting one file format to another.
- Where one of the protocols is *evolving*, you're definitely going to need to keep releasing new versions. The functionality of a Calculator app on my phone remains the same, but new versions have to be released as the phone APIs change, screens change resolution and so on.
- tbd

Where boundaries

tbd Trying to create a complex, fractal surface. User requirements are fractal in nature.

## Object-Relational Mapping

For example, Object Relational Mapping (ORM) has long been a problem in software. This is [Boundary-Crossing] software trying to bridge the gap between Relational Databases and Object-Oriented Languages like [Java]. Building a *general* library that does this and is useful tbd said:

'Object/Relational Mapping is the Vietnam of Computer Science'  
- Ted Neward<sup>28</sup>

This is a particularly difficult problem because the two ecosystems are so *rich* and *complex* in the functionality they expose. But what are the alternatives?

- Either back to building functionality within the database again, using stored procedures
- Building Object Oriented Databases. It's interesting that neither of these really worked out.
- Custom-building the bridge between the systems, one database call at-a-time in your own software.

This is tbd hobson's choice, there is strong debate about whether ORM is a worse trade of mitigated Boundary Risk for attendant Complexity Risk or not, and clearly will depend on your circumstances.

---

<sup>28</sup><http://blogs.tedneward.com/post/the-vietnam-of-computer-science/>

## Scala

Mapping between complex boundaries is especially difficult if the boundaries are evolving and changing as you go. This means in ecosystems that are changing rapidly, you are unlikely to be able to create lasting bridges between them. Given that Java is an old, large and complex ecosystem, you would imagine that it would have a slow-enough rate of change that abstracting technologies can be built on top of it safely.

Indeed, we see that happening with Clojure and Kotlin, two successful languages built on top of the Java Virtual Machine (JVM) and offering compatibility with it.

Scala is arguably the first mainstream language that tried to do the same thing: it is trying to build a Functional Programming paradigm on top of the Java Virtual Machine (JVM), which traditionally has an Object Oriented paradigm.

The problem faced by Scala is that Java didn't stay still: as soon as they demonstrated some really useful features in Scala (i.e. stream-based processing), Java moved to include this new functionality too. If they hadn't, the developer community would have slowly drifted away and used Scala instead.

So, in a sense, Scala is a *success story*: they were able to force change to Java. But, once Java had changed, Scala was in the difficult position of having two sets of competing features in the platform: the existing Scala streams, and the new Java streams.

Clojure can interop with Java because on one side, the boundary is simple: lisp is a simple language which lends itself to reimplementation within other platforms. Therefore, the complexity of the bridge is *simple*: all that needs to be provided is a way to call methods from Java to clojure.

Scala and Java have a complex relationship because Scala creates its own complex boundary: it is syntactically and functionally a broad language with lots of features. And so is Java. Mapping from one to the other is therefore

for interop here. Why is one so different from the other?

## Browsers

Web browsers are another surprisingly complex boundary. They have to understand the following protocols:

- HTTP for loading resources (as we already reviewed in Complexity Risk)
- HTML Pages, for describing the content of web pages Complexity Risk
- Various image formats
- Javascript for web-page *interactivity*
- CSS for web-page styling, animation and so on.
- ... and several others.

Handling any one of these protocols alone is a massive endeavour, so browsers are built on top of Software Libraries which handle each concern, for example, Networking Libraries, Parsers and so on.

One way of looking at the browser is that it is a *function*, where those elements listed above are the *inputs* to the function, and the output is *what is displayed on the screen*, as shown in the image below.

tbd. browser as a function

There are three specific problems that make this a really complex boundary:

1. All of the standards above are *evolving and improving*. And, although HTML5 (say) is a reasonably well-specified standard, in reality, web pages tend not to adhere exactly to the letter of it. People make mistakes in the HTML they write, and it's up to the browser to try and figure out what they *meant* to write, rather than what they did write. This makes the *input* to the function extremely complex.
2. Similarly, the *output* of the function is not well defined either, and relies a lot on people's *subjective aesthetic judgement*. For example, if you insert a <table> into an HTML page, the specification doesn't say anything about exactly how big the table should be, the size of its borders, the spacing of the content and so on. At least, initially, *none* of this was covered by the HTML Specification. The CSS specification is over time clearing this up, but it's not *exactly nailed down*, which means...
3. That because there are various different browsers (Chrome, Safari, Internet Explorer, Microsoft Edge, Firefox etc.) and each browser has multiple different versions, released over a period of many years, you cannot, as a web-page developer know, *a priori* what your web-page will look like to a user.

As developers trying to build software to be delivered over the internet, this is therefore a source of common Boundary Risk. If you were trying to build

software to work in *all browsers* and *all versions*, this problem would be nearly insurmountable. So, in order to tackle this risk, we do the following:

- We pick a small (but commonly used) subset of browsers, and use features from the specifications that we know commonly work in that subset.
- We test across the subset. Again, testing is *harder than it should be*, because of problem 2 above, that the expected output is not exactly defined. This generally means you have to get humans to apply their *subjective aesthetic judgement*, rather than getting machines to do it.
- There is considerable pressure on browser developers to ensure consistency of behaviour across the implementations. If all the browsers work the same, then we don't face the Boundary Risk of having to choose just one to make our software work in. However, it's not always been like this...

## 10.9 Vendor Lock-In

In the late 1990s, faced with the emergence of the nascent World Wide Web, and the Netscape Navigator browser, Microsoft adopted a strategy known as Embrace and Extend. The idea of this was to subvert the HTML standard to their own ends by *embracing* the standard and creating their own browser (Internet Explorer) and then *extending* it with as much functionality as possible, which would then *not work* in Netscape Navigator. They then embarked on a campaign to try and get everyone to "upgrade" to Internet Explorer. In this way, they hoped to "own" the Internet, or at least, the software of the browser, which they saw as analogous to being the "operating system" of the Internet, and therefore a threat to their own operating system, Windows.

There are two questions we need to ask about this, from the point-of-view of understanding Boundary Risk:

1. Why was this a successful strategy?
2. Why did they stop doing this?

Let's look at the first question then. Yes, it was a successful strategy. In the 1990s, browser functionality was rudimentary. Developers were *desperate* for more features, and for more control over what appeared on their web-pages. And, Internet Explorer (IE) was a free download (or, bundled with Windows). By shunning other browsers and coding just for IE, developers

pushed Boundary Risk to the consumers of the web pages and in return mitigated Dependency Fit Risk: they were able to get more of the functionality they wanted in the browser.

It's worth pointing out, *this was not a new strategy*:

- Processor Chip manufacturers had done something similar in the tbds: by providing features (instructions) on their processors that other vendors didn't have, they made their processors more attractive to system integrators. However, since the instructions were different on different chips, this created Boundary Risk for the integrators. Intel and Microsoft were able to use this fact to build a big ecosystem around Windows running on Intel chips (so called, Wintel).
- We have two main *mobile* ecosystems: Apple's [iOS] and Google's Android, which are both *very* different and complex ecosystems with large, complex boundaries. They are both innovating as fast as possible to keep users happy with their features. Tools like Xamarin exist which allow you to build
- Currently, Amazon Web Services (AWS) are competing with Microsoft Azure and [Google tbd] over building tools for Platform as a Service (PaaS) (running software in the cloud). They are both racing to build new functionality, but at the same time it's hard to move from one vendor to another as there is no standardization on the tools.
- As we saw above, Database vendors tried to do the same thing with features in the database. Oracle particularly makes money over differentiating itself from competitors by providing features that other vendors don't have. Tom tbd provides a compelling argument for using these features thus:

tbd.

The next question, is why did Microsoft *stop* pursuing this strategy? It seems that the answer is because they were made to. tbd.

## 10.10 Everyday Boundary Risks

Boundary Risk occurs all the time. Let's look at some ways:

- **Configuration:** When software has to be deployed onto a server, there has to be configuration (usually on the command line, or via configuration property files) in order to bridge the boundary between the

*environment it's running in and the software being run.* Often, this is setting up file locations, security keys and passwords, and telling it where to find other files and services.

- **Integration Testing:** Building a unit test is easy. You are generally testing some code you have written, aided with a testing framework. Your code and the framework are both written in the same language, which means low boundary risk. But, to *integration test* you need to step outside this boundary and so it becomes much harder. This is true whether you are integrating with other systems (providing or supplying them with data) or parts of your own system (say testing the client-side and server parts together).
- **User Interface Testing:** If you are supplying a user-interface, then the interface with the user is already a complex, under-specified risky protocol. Although tools exist to automate UI testing (such as Selenium, these rarely satisfactorily mitigate this protocol risk: can you be sure that the screen hasn't got strange glitches, that the mouse moves correctly, that the proportions on the screen are correct on all browsers?
- **Jobs:** When you pick a new technology to learn and add to your CV, it's worth keeping in mind how useful this will be to you in the future. It's career-limiting to be stuck in a dying ecosystem and need to retrain.
- **Teams:** if you're given license to build a new product within an existing team, are you creating Boundary Risk by using tools that the team aren't familiar with?
- **Organisatations:** Getting teams or departments to work with each other often involves breaking down Boundary Risk. Often the departments use different tool-sets or processes, and have different goals making the translation harder. tbd

## Boundary Risk and Change

You can't always be sure that a dependency now will always have the same guarantees in the future:

- **Ownership changes** Microsoft buys Github. What will happen to the ecosystem around github now?
- **Licensing changes.** (e.g. Oracle<sup>29</sup> buys Tangosol who make Coherence<sup>30</sup> for example). Having done this, they increase the licensing costs of Tangosol to huge levels, milking the Cash Cow of the installed user-base, but ensuring no-one else is likely to use it.

---

<sup>29</sup><http://oracle.com>

<sup>30</sup>[https://en.wikipedia.org/wiki/Oracle\\_Coherence](https://en.wikipedia.org/wiki/Oracle_Coherence)

- **Better alternatives become available:** As a real example of this, I began a project in 2016 using Apache Solr. However, in 2018, I would probably use ElasticSearch<sup>31</sup>. In the past, I've built websites using Drupal and then later converted them to use WordPress.

## 10.11 Patterns In Boundary Risk

In Feature Risk, we saw that the features people need change over time. Let's get more specific about this:

- Human need is Fractal. This means that over time, software products have evolved to more closely map to human needs. Software that would have delighted us ten years ago lacks the sophistication we expect today.
- Software and hardware are both improving with time, due to evolution and the ability to support greater and greater levels of complexity.
- Abstractions build too. As we saw in Process Risk, we *encapsulate* earlier abstractions in order to build later ones.

If all this is true, the only thing we can expect in the future is that the lifespan of any ecosystem will follow an arc through creation, adoption, growth, use and finally either be abstracted over or abandoned.

tbd diagram.

Although our discipline is a young one, we should probably expect to see "Software Archaeology" in the same way as we see it for biological organisms. Already we can see the dead-ends in the software evolutionary tree: COBOL and BASIC languages, CASE systems. Languages like FORTH live on in PostScript, SQL is still embedded in everything

Boundary risk is *inside* and *outside*

---

<sup>31</sup><https://en.wikipedia.org/wiki/Elasticsearch>

# Agency Risk

Coordinating a team is difficult enough when everyone on the team has a single Goal. But, people have their own goals, too. Sometimes, the goals harmlessly co-exist with the team's goal, but other times they don't.

This is Agency Risk. This term comes from finance and refers to the situation where you (the "principal") entrust your money to someone (the "agent") in order to invest it, but they don't necessarily have your best interests at heart. They may instead elect to invest the money in ways that help them, or outright steal it.

"This dilemma exists in circumstances where agents are motivated to act in their own best interests, which are contrary to those of their principals, and is an example of moral hazard." - Principal-Agent Problem, *Wikipedia*<sup>1</sup>

The less visibility you have of the agent's activities, the bigger the risk. However, the whole *point* of giving the money to the agent was that you would have to spend less time and effort managing it.

Agency Risk clearly includes the behaviour of Bad Actors<sup>2</sup>. But, this is a very strict definition of Agency Risk. In software development, we're not lending each other money, but we are being paid by the project sponsor, so they are assuming Agency Risk by employing us.

As we saw in the previous chapter on Process Risk, Agency Risk doesn't just apply to people: it can apply to *running software* or *whole teams*.

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Principalagent\\_problem](https://en.wikipedia.org/wiki/Principalagent_problem)

<sup>2</sup>[https://en.wiktionary.org/wiki/bad\\_actor](https://en.wiktionary.org/wiki/bad_actor)

**Figure 11.1: Mitigating Agency Risk Through Monitoring**

Let's look at some examples of borderline Agency Risk situations, in order to sketch out where the domain of this risk lies.

## 11.1 Personal Lives

We can't (shouldn't) expect people on a project to sacrifice their personal lives for the success of the project, right? Except that "Crunch Time"<sup>3</sup> is exactly how some software companies work:

"Game development... requires long working hours and dedication from their employees. Some video game developers (such as Electronic Arts) have been accused of the excessive invocation of "crunch time". "Crunch time" is the point at which the team is thought to be failing to achieve milestones needed to launch a game on schedule. " - Crunch Time, *Wikipedia*

People taking time off, going to funerals, looking after sick relatives and so on are all Agency Risk, but they should be *accepted* on the project. They are a necessary Attendant Risk of having *staff* rather than *slaves*.

## 11.2 The Hero

"The one who stays later than the others is a hero." - Hero Culture, *Ward's Wiki*<sup>4</sup>

Conversely, Heroes put in more hours and try to rescue projects single-handedly, often cutting corners like team communication and process in order to get there.

Sometimes, projects don't get done without heroes. But other times, the hero has an alternative agenda than just getting the project done:

<sup>3</sup>[https://en.wikipedia.org/wiki/Video\\_game\\_developer#%22Crunch\\_time%22](https://en.wikipedia.org/wiki/Video_game_developer#%22Crunch_time%22)

<sup>4</sup><http://wiki.c2.com/?HeroCulture>

- A need for control, and for their own vision.
- A preference to work alone.
- A desire for recognition and acclaim from colleagues.
- For the job security of being a Key Man<sup>5</sup>.

A team *can* make use of heroism, but it's a double-edged sword. The hero can becomes a bottleneck to work getting done, and because want to solve all the problems themselves, they under-communicate.

### 11.3 Consultancies

When you work with an external consultancy, there is *always* more Agency Risk than with a direct employee. This is because as well as your goals and the employee's goals, there is also the consultancy's goals.

This is a good argument for not using consultancies, but sometimes the technical expertise they bring can outweigh this risk.

Also, try to look for *hungry* consultancies: if you being a happy client is valuable to them, they will work at a discount (either working cheaper, harder or longer or more carefully) as a result.

### 11.4 CV Building

This is when someone decides that the project needs a dose of "Some Technology X", but in actual fact, this is either completely unhelpful to the project (incurring large amounts of Complexity Risk), or merely less useful than something else.

It's very easy to spot CV building: look for choices of technology that are incongruently complex compared to the problem they solve, and then challenge by suggesting a simpler alternative.

### 11.5 Career Risk

### 11.6 Devil Makes Work

Heroes can be useful, but *underused* project members are a nightmare. The problem is, people who are not fully occupied begin to worry that actually, the team would be better off without them, and then wonder if their jobs are at risk.

---

<sup>5</sup>[https://en.wikipedia.org/wiki/Key\\_person\\_insurance](https://en.wikipedia.org/wiki/Key_person_insurance)

The solution to this is “busy-work”: finding tasks that, at first sight, look useful, and then delivering them in an over-elaborate way (Gold Plating)) that’ll keep them occupied. This will leave you with more Complexity Risk than you had in the first place.

Even if they don’t worry about their jobs, doing this is a way to stave off boredom.

## 11.7 Pet Projects

A project, activity or goal pursued as a personal favourite, rather than because it is generally accepted as necessary or important. -  
Pet Project, *Wiktionary*<sup>6</sup>

Sometimes, budget-holders have projects they value more than others without reference to the value placed on them by the business. Perhaps the project has a goal that aligns closely with the budget holder’s passions, or its related to work they were previously responsible for.

Working on a pet project usually means you get lots of attention (and more than enough budget), but due to Map and Territory Risk, it can fall apart very quickly under scrutiny.

## 11.8 Morale Risk

Morale, also known as Esprit de Corps is the capacity of a group’s members to retain belief in an institution or goal, particularly in the face of opposition or hardship - Morale, *Wikipedia*<sup>7</sup>

Sometimes, the morale of the team or individuals within it dips, leading to lack of motivation. Morale Risk is a kind of Agency Risk because it really means that a team member or the whole team isn’t committed to the Goal, may decide their efforts are best spent elsewhere. Morale Risk might be caused by:

- External factors: Perhaps the employees’ dog has died, or they’re simply tired of the industry, or are not feeling challenged.
- If the team don’t believe a goal is achievable, they won’t commit their full effort to it. This might be due to a difference in the evaluation of the risks on the project between the team members and the leader.

---

<sup>6</sup>[https://en.wiktionary.org/wiki/pet\\_project](https://en.wiktionary.org/wiki/pet_project)

<sup>7</sup><https://en.wikipedia.org/wiki/Morale>

- If the goal isn't considered sufficiently worthy, or the team isn't sufficiently valued.
- In military science, a second meaning of morale is how well supplied and equipped a unit is. This would also seem like a useful reference point for IT projects. If teams are under-staffed or under-equipped, this will impact on motivation too.

## 11.9 Hubris & Ego

It seems strange that humans are over-confident. You would have thought that evolution would drive out this trait but apparently it's not so:

"Now, new computer simulations show that a false sense of optimism, whether when deciding to go to war or investing in a new stock, can often improve your chances of winning." - Evolution of Narcissism, *National Geographic*<sup>8</sup>

In any case, humans have lots of self-destructive tendencies that *haven't* been evolved away, and we get by.

Development is a craft, and ideally, we'd like developers to take pride in their work. Too little pride means lack of care, but too much pride is *hubris*, and the belief that you are better than you really are. Who does hubris benefit? Certainly not the team, and not the goal, because hubris blinds the team to hidden risks that they really should have seen.

Although over-confidence might be a useful trait when bargaining with other humans, the thesis of everything so far is that Meeting Reality will punish your over-confidence again and again.

Perhaps it's a little unfair to draw out one human characteristic for attention. After all, we are riddled with biases. There is probably an interesting article to be written about the effects of different biases on the software development and project management processes. (This task is left as an exercise for the reader.)

## 11.10 Software Processes And Teams

Agency Risk doesn't just refer to people - it refers to anything which has agency over its actions.

---

<sup>8</sup><https://news.nationalgeographic.com/news/2011/09/110914-optimism-narcissism-overconfidence-hubris-evolution-science-nature/>

"Agency is the capacity of an actor to act in a given environment. . . Agency may either be classified as unconscious, involuntary behavior, or purposeful, goal directed activity (intentional action)." - Agency, Wikipedia<sup>9</sup>

There is significant Agency Risk in running software *at all*. Since computer systems follow rules we set for them, we shouldn't be surprised when those rules have exceptions that lead to disaster. For example:

- A process continually writing log files until the disks fill up, crashing the system.
- Bugs causing data to get corrupted, causing financial loss.
- Malware infecting a system, and sending your passwords and data to undesirables.

Agency Risk also covers *whole teams* too. It's perfectly possible that a team within an organisation develops Goals that don't align with those of the overall organisation. For example:

- A team introduces excessive Bureaucracy in order to avoid work it doesn't like.
- A team gets obsessed with a particular technology, or their own internal process improvement, at the expense of delivering business value.
- A marginalised team forces their services on other teams in the name of "consistency". (This can happen a lot with "Architecture", "Branding" and "Testing" teams, sometimes for the better, sometimes for the worse.)

## 11.11 It's About Goals

We've looked here at some illustrative examples of Agency Risk. But as we stated at the beginning, Agency Risk at any level comes down to differences of Goals between the different agents, whether they are *people, teams or software*.

So, having looked at agents *individually*, it's time to look more closely at Goals, and the Attendant Risks when aligning them amongst multiple agents.

On to Coordination Risk . . .

---

<sup>9</sup>[https://en.wikipedia.org/wiki/Agency\\_\(philosophy\)](https://en.wikipedia.org/wiki/Agency_(philosophy))

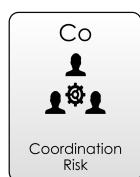

- Risks due to the fact that things you depend on have agency, and they have their own goals to pursue.

*Figure 11.2: Agency Risk*

## Coordination Risk

Coordination Risk is the risk that, a group of people (or processes), maybe with a similar Goal In Mind they can fail to coordinate on a way to meet this goal and end up making things worse. Coordination Risk is embodied in the phrase “Too Many Cooks Spoil The Broth”: more people, opinions or agents often make results worse.

- Risks that a group of agents cannot work together in a mutually beneficial way, and their behaviour devolves into competition.

*Figure 12.1: Coordination Risk*

As in Agency Risk, we are going to use the term *agent*, which refers to anything with agency<sup>1</sup> in a system to decide it's own fate. That is, an agent has an Internal Model, and can take actions based on it. Here, we're going to work on the assumption that the agents *are* working towards a common Goal, even though in reality it's not always the case, as we saw in the chapter on Agency Risk.

In this chapter, we'll first build up A Model Of Coordination Risk and what exactly coordination means and why we do it. Then, we'll look at some classic Problems of Coordination. Then, we're going to consider agency at several different levels (because of Scale Invariance) . We'll look at: - Team

<sup>1</sup><https://github.com/risk-first/website/wiki/Agency-Risk#software-processes-and-teams>

Decision Making, - Living Organisms, - Larger Organisations and the staff within them, - and Software Processes.

... and we'll consider how Coordination Risk is a problem at each scale.

But for now, let's crack on and examine where Coordination Risk comes from.

## 12.1 A Model Of Coordination Risk

Earlier, in Dependency Risk, we looked at various resources (time, money, people, events etc) and showed how we could Depend On Them, taking on risk. Here, however, we're looking at the situation where there is *competition for those dependencies*, that is, Scarcity Risk: other parties want to use them in a different way.

### Competition

The basic problem of Coordination Risk, then, is *competition*. Sometimes, competition is desirable (such as in sports and in markets), but sometimes competition is a waste and cooperation would be more efficient. Without coordination, we would deliberately or accidentally compete for the same Dependencies, which is wasteful.

Why is this wasteful?

One argument could come from Diminishing Returns<sup>2</sup>, which says that the earlier units of a resource (say, chocolate bars) give you more benefit than later ones.

We can see this in the graph below. Let's say A and B compete over a resource, of which there are 5 units available. For every extra A takes, B loses one. The X axis shows A's consumption of the resource, so the biggest benefit to A is in the consumption of the first unit.

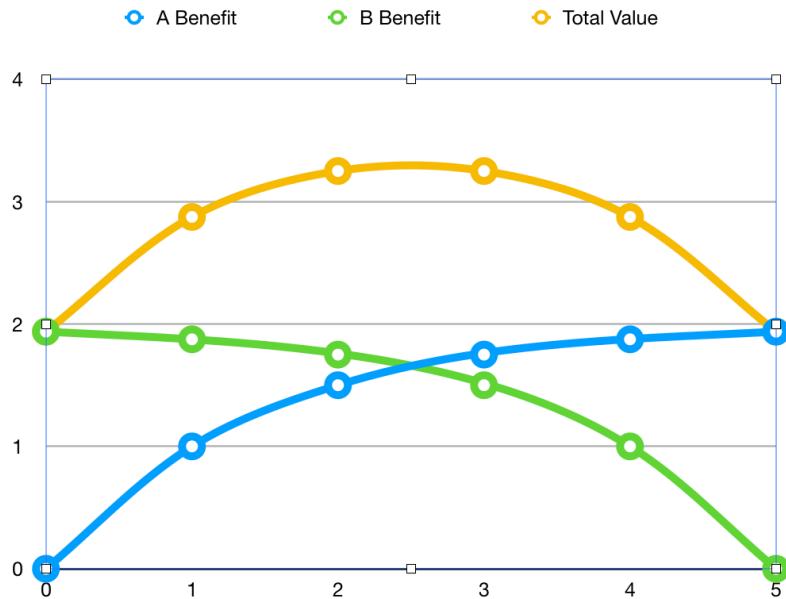

As you can see, by *sharing*, it's possible that the *total benefit* is greater than it can be for either individual. But sharing requires coordination. Further, the more competitors involved, the *worse* a winner-take-all outcome is for total benefit.

Just two things are needed for competition to occur:

- Individual agents, trying to achieve Goals.
- Scarce Resources, which the agents want to use as Dependencies.

---

<sup>2</sup>[https://en.wikipedia.org/wiki/Diminishing\\_returns](https://en.wikipedia.org/wiki/Diminishing_returns)

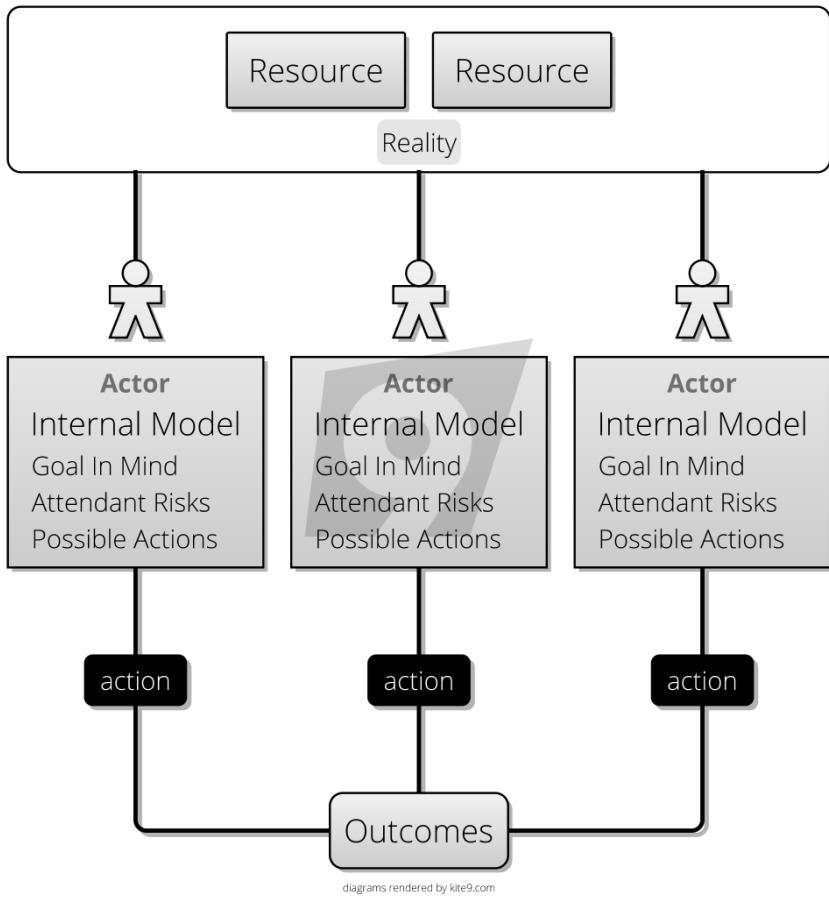

*Figure 12.2: Sharing Resources. 5 units are available, and the X axis shows A's consumption of the resource. B gets whatever remains. Total benefit is maximised somewhere in the middle*

## Coordination via Communication

The only way that the agents can move away from competition towards coordination is via Communication, and this is where their coordination problems begin.

You might think, therefore, that this is just another type of Communication Risk problem, and that's often a part of it, but even with synchronized Internal Models, coordination risk can occur. Imagine the example of people all trying to madly leave a burning building. They all have the same information (the building is on fire). If they coordinate, and leave in an orderly fashion, they might all get out. If they don't, and there's a scramble for the door, more people might die.

But commonly, Coordination Risk occurs where people have different ideas about how to achieve a goal, and they have different ideas because they have different evaluations of the Attendant Risk. As we saw in the chapter on Communication Risk, we can only hope to synchronize Internal Models if there are high-bandwidth Channels available for communication.

*Figure 12.3: A model of competition: scarce resources, and individual agents competing for them.*

## 12.2 Problems Of Coordination

Let's unpack this idea, and review some classic problems of coordination, none of which can be addressed without good communication:

1. **Merging Data.** If you are familiar with the source code control system, Git, you will know that this is a *distributed* version control system. That means that two or more people can propose changes to the same files without knowing about each other. This means that at some later time, Git then has to merge (or reconcile) these changes together. Git is very good at doing this automatically, but sometimes, different people can independently change the same lines of code and these will have to

be merged manually. In this case, a human arbitrator “resolves” the difference, either by combining the two changes or picking a winner.

2. **Consensus.** Making group decisions (as in elections) is often decided by votes. But having a vote is a coordination issue, and requires that everyone has been told the rules:
  - Where will the vote be held?
  - How long do you provide for the vote?
  - What do you do about absentees?
  - What if people change their minds in the light of new information?
  - How do you ensure everyone has enough information to make a good decision?
3. **Factions.** Sometimes, it’s hard to coordinate large groups at the same time, and “factions” can occur. That the world isn’t a single big country is probably partly a testament to this: countries are frequently separated by geographic features that prevent the easy flow of communication (and force). We can also see this in distributed systems, with the “split brain”) problem. This is where a network of processes becomes disconnected (usually due to a network failure between data centers), and you end up with two, smaller networks with different knowledge. We’ll address in more depth later.
4. Resource Allocation<sup>3</sup>: Ensuring that the right people are doing the right work, or the right resources are given to the right people is a coordination issue. On a grand scale, we have Logistics, and Economic Systems<sup>4</sup>. On a small scale, the office’s *room booking system* solves the coordination issue of who gets a meeting room using a first-come-first-served booking algorithm.
5. Deadlock: Deadlock refers to a situation where, in an environment where multiple parallel processes are running, the processing stops and no-one can make progress because the resources each process needs are being reserved by another process. This is a specific issue in Resource Allocation, but it’s one we’re familiar with in the computer science industry. Compare with Gridlock<sup>5</sup>, where traffic can’t move because other traffic is occupying the space it wants to move to already.

---

<sup>3</sup>[https://en.wikipedia.org/wiki/Resource\\_allocation](https://en.wikipedia.org/wiki/Resource_allocation)

<sup>4</sup>[https://en.wikipedia.org/wiki/Economic\\_system](https://en.wikipedia.org/wiki/Economic_system)

<sup>5</sup><https://en.wikipedia.org/wiki/Gridlock>

6. **Race Conditions:** A race condition is where we can't be sure of the result of a calculation, because it is dependent on the ordering of events within a system. For example, two separate threads writing the same memory at the same time (one ignoring and over-writing the work of the other) is a race.
7. **Contention:** Where there is Scarcity Risk for a Dependency, we might want to make sure that everyone gets fair use of it, by taking turns, booking, queueing and so on. As we saw in Scarcity Risk, sometimes, this is handled for us by the Dependency itself. However if it isn't, it's the *users* of the dependency who'll need to coordinate to use the resource fairly, again, by communicating with each other.

## 12.3 Team Decision Making

Within a team, Coordination Risk is at its core about resolving Internal Model conflicts in order that everyone can agree on a Goal In Mind and cooperate on getting it done. Therefore, Coordination Risk is worse on projects with more members, and worse in organizations with more staff.

If you are engaged in a solo project, do you suffer from Coordination Risk at all? Maybe: sometimes, you can feel "conflicted" about the best way to solve a problem. And weirdly, usually *not thinking about it* helps. Sleeping too. (Rich Hickey calls this "Hammock Driven Development"<sup>6</sup>). This is probably because, unbeknownst to you, your subconscious is furiously communicating internally, trying to resolve these conflicts itself, and will let you know when it's come to a resolution.

Vroom and Yetton<sup>7</sup> introduced a model of group decision making which delineated five different styles of decision making within a team. These are summarised in the table below (AI, AII, CI, CII, GII). To this, I have added a sixth (UI), which is the *uncoordinated* option, where everyone competes. In the accompanying diagrams I have adopted the following convention: - Thin lines with arrow-heads show a flow of *information*, either one-way or two-way. - Thick lines show a flow of *opinion*. - Boxes with corners are *decision makers*, whereas curved corners don't have a part in the decision.

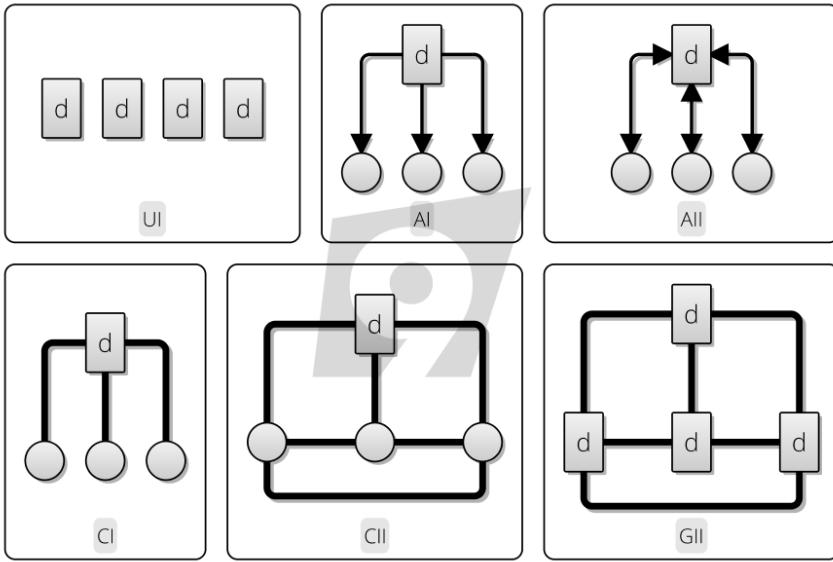

At the top, you have the *least* consultative styles, and at the bottom, the *most*. At the top, decisions are made with just the leader's Internal Model but moving down, the Internal Models of the rest of the team are increasingly brought into play.

---

<sup>6</sup><https://www.youtube.com/watch?v=f84n5oFoZBc>

<sup>7</sup>[https://en.wikipedia.org/wiki/Vroom–Yetton\\_decision\\_model](https://en.wikipedia.org/wiki/Vroom–Yetton_decision_model)

Type	People Involved In Decision	Opinions	Channels Of Communication	Coordination Risk	Description
UI	1	1	0	Competition	No Coordination
AI	1	1	s (One message to each subordinate)	Maximum Coordination Risk	Autocratic, top-down
AII	1	1	2 × s (Messages from/to each subordinate)		Autocratic, with information flow up.
CI	1		1 + s	> 2 × s	Individual Consultations
CII	1		1 + s	> s2	Group Consultation
GII	1 + s		1 + s	> s2	Group Consultation with voting
					Risk, Schedule Risk

diagrams rendered by kite9.com

**Figure 12.4: Vroom And Yetton Decision Making Styles.** “d” indicates authority in making a decision. Thin lines with arrow-heads show information flow, whilst thick lines show opinions being passed around.

The decisions at the top are faster, but don't do much for mitigating **Coordination Risk**. The ones below take longer, (incurring Schedule Risk) but mitigate more **Coordination Risk**. Group decision-making inevitably involves everyone *learning*, and improving their Internal Models.

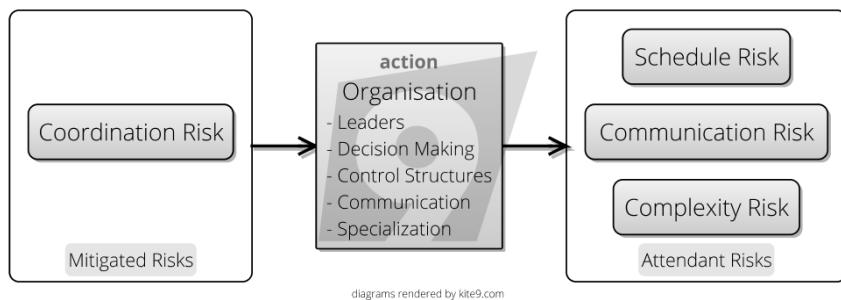

The trick is to be able to tell which approach is suitable at which time. Everyone is expected to make decisions *within their realm of expertise*: you can't have developers continually calling meetings to discuss whether they should be using an Abstract Factory<sup>8</sup> or a Factory Method<sup>9</sup>, this would waste time. The critical question is therefore, “what's the biggest risk?” - Is the Coordination Risk greater? Are we going to suffer Dead End Risk if the decision is made wrongly? What if people don't agree with it? Poor leadership has an impact on Morale too. - Is the Schedule Risk greater? If you have a 1-hour meeting with eight people to decide a decision, that's *one man day* gone right there: group decision making is *expensive*.

Hopefully, this model shows how *organisation* can reduce Coordination Risk. But, to make this work, we need more *communication*, and this has attendant

<sup>8</sup>[https://en.wikipedia.org/wiki/Abstract\\_factory\\_pattern](https://en.wikipedia.org/wiki/Abstract_factory_pattern)

<sup>9</sup>[https://en.wikipedia.org/wiki/Factory\\_method\\_pattern](https://en.wikipedia.org/wiki/Factory_method_pattern)

complexity and time costs. So, we can draw this diagram of our move on the Risk Landscape:

*Figure 12.5: Coordination Risk traded for Complexity Risk, Schedule Risk and Communication Risk*

## Staff As Agents

Staff in a team have a dual nature: they are **Agents** and **Resources** at the same time. The team depends on staff for their resource of *labour*, but they're also part of the decision making process of the team, because they have agency over their own actions.

Part of Coordination Risk is about trying to mitigate differences in Internal Models. So it's worth considering how varied people's models can be:

- Different skill levels
- Different experiences
- Expertise in different areas
- Preferences
- Personalities

The job of harmonizing this on a project would seem to fall to the team leader, but actually people are self-organising to some extent. This process is called Team Development<sup>10</sup>:

"The forming–storming–norming–performing model of group development was first proposed by Bruce Tuckman in 1965, who said that these phases are all necessary and inevitable in order for the team to grow, face up to challenges, tackle problems, find solutions, plan work, and deliver results." - Tuckman's Stages Of Group Development, *Wikipedia*

Specifically, this describes a process whereby a new group will form and then be required to work together. In the process, they will have many *disputes*.

<sup>10</sup>[https://en.wikipedia.org/wiki/Tuckman%27s\\_stages\\_of\\_group\\_development](https://en.wikipedia.org/wiki/Tuckman%27s_stages_of_group_development)

Ideally, the group will resolve these disputes internally and emerge as a *Team*, with a common Goal In Mind.

They can be encouraged with orthogonal practices such as team-building exercises<sup>11</sup> (generally, submitting everyone to extreme experiences in order to bond them together). With enough communication bandwidth and detente, a motivated team will self-organise code reviews, information exchange and improve their practices.

As described above, the job of Coordination is Resource Allocation, and so the skills of staff can potentially be looked at as resources to allocate. This means handling Coordination Risk issues like:

- People leaving, taking their Internal Models and expertise with them Key Man Risk.
- People requiring external training, to understand new tools and techniques Learning-Curve Risk.
- People being protective about their knowledge in order to protect their jobs Agency Risk.
- Where there are mixed ability levels, senior developers not helping juniors as it “slows them down”.
- People not getting on and not helping each other.

“As a rough rule, three programmers organised into a team can do only twice the work of a single programmer of the same ability - because of time spent on coordination problems.” - Gerald Weinberg, The Psychology of Computer Programming<sup>12</sup>

## 12.4 In Living Organisms

Vroom and Yetton’s organisational style isn’t relevant to just teams of people. We can see it in the natural world too. Although *the majority* of cellular life on earth (by weight) is single celled organisms<sup>13</sup>, the existence of *humans* (to pick a single example) demonstrates that sometimes it’s better to try to mitigate Coordination Risk and work as a team, accepting the Complexity Risk and Communication Risk this entails. As soon as cells start working together, they either need to pass *resources* between them, or *control* and *feedback*.

For example, in the human body, we have various systems<sup>14</sup>:

<sup>11</sup>[https://en.wikipedia.org/wiki/Team\\_building](https://en.wikipedia.org/wiki/Team_building)

<sup>12</sup>[https://en.wikipedia.org/wiki/Gerald\\_Weinberg](https://en.wikipedia.org/wiki/Gerald_Weinberg)

<sup>13</sup>[http://www.stephenjaygould.org/library/gould\\_bacteria.html](http://www.stephenjaygould.org/library/gould_bacteria.html)

<sup>14</sup>[https://en.wikipedia.org/wiki/List\\_of\\_systems\\_of\\_the\\_human\\_body](https://en.wikipedia.org/wiki/List_of_systems_of_the_human_body)

- The Respiratory System<sup>15</sup> which is responsible for ensuring that Red Blood Cells<sup>16</sup> are replenished with Oxygen, as well as disposing of Carbon Dioxide.
- The Digestive System<sup>17</sup> which is responsible for extracting nutrition from food and putting them in our Blood Plasma<sup>18</sup>.
- The Circulatory System<sup>19</sup> which is responsible for moving blood cells to all the rest of the body.
- The Nervous System<sup>20</sup> which is responsible for collecting information from all the parts of the body, dealing with it in the Brain<sup>21</sup> and issuing commands.
- The Motor System<sup>22</sup> which contains muscles and bones, and allows us to move about.

... and many others. Each of these systems contains organs, which contain tissues, which contain cells of different types. (Even cells are complex systems containing multiple different, communicating sub-systems.) There is huge Complexity Risk here: the entire organism fails if one of these systems fail (they are Single Points Of Failure, although we can get by despite the failure of one lung or one leg say).

Some argue<sup>23</sup> that the human nervous system is the most complex known artifact in the universe: there is huge attendant Communication Risk to running the human body. But, given the success of humanity as a species, you must conclude that these steps on the evolutionary Risk Landscape have benefitted us in our ecological niche.

The key observation from looking at biology is this: most of the cells in the human body *don't get a vote*. Muscles in the motor system have an **AI** or **AII** relationship with the brain - they do what they are told, but there are often nerves to report pain back. The only place where **CII** or **GII** *could* occur is in our brains, when we try to make a decision and weigh up the pros and cons.

This means that there is a deal: *most* of the cells in our body accede control of their destiny to "the system". Living within the system of the human body is a better option than going it alone. Occasionally, due to mutation, we can end

---

diagrams rendered by kite9.com

*Figure 12.6: Hierarchy of Function in the Human Body*

up with Cancer<sup>24</sup>, which is where one cell genetically “forgets” its purpose in the whole system and goes back to selfish individual self-replication (UI). We have White Blood Cells<sup>25</sup> in the body to shut down this kind of behaviour and try to kill the rogue cells. In the same way, society has a police force to stop undesirable behaviour amongst its citizens.

## 12.5 Large Organisations

Working in a large organisation often feels like being a cell in a larger organism. Just as cells live and die, but the organism goes on, in the same way, workers come and go from a large company but the organisation goes on. By working in an organisation, we give up self-control and competition and accept **AI** and **AII** power structures above us, but we trust that there is symbiotic value creation on both sides of the employment deal.

Less consultative decision making styles are more appropriate than when we don't have the luxury of high-bandwidth channels for discussion, or when the number of parties rises above a room-full of people. As you can see from the table above, for **CII** and **GII** decision-making styles, the amount of communication increases non-linearly with the number of participants, so we need something simpler. As we saw in the Complexity Risk chapter, hierarchies are an excellent way of economizing on number of different communication channels, and we use these frequently when there are lots of parties to coordinate.

In large organisations, teams are created and leaders chosen for those teams precisely to mitigate Communication Risk. We're all familiar with this: control of the team is ceded to the leader, who takes on the role of 'handing down' direction from above, but also 'reporting up' issues that cannot be resolved within the team. In Vroom and Yetton's model, this is moving from a **GII** or **CII** to an **AI** or **AII** style of leadership.

As shown in the diagram above, we end up with a hierarchy of groups, each having its own decision-making style. The team leader at the bottom level is a *decision maker* within his team, but moving up, doesn't have decision making power in the next team up.. and so on.

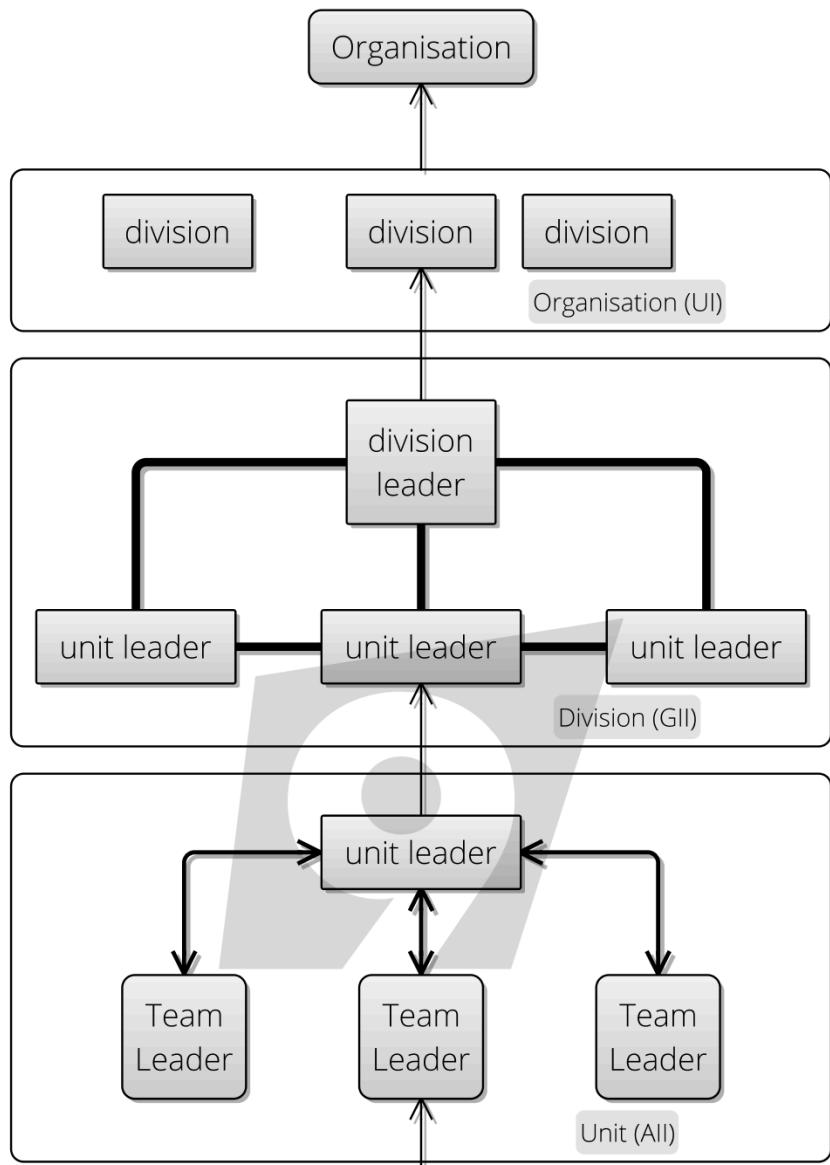

Sometimes, parts of an organisation are encouraged *not* to coordinate, but to compete. In the diagram above, we have an M-Form<sup>26</sup> organisation, composed of *competing divisions*.

---

<sup>24</sup><https://en.wikipedia.org/wiki/Cancer>

<sup>25</sup>[https://en.wikipedia.org/wiki/White\\_blood\\_cell](https://en.wikipedia.org/wiki/White_blood_cell)

<sup>26</sup>[https://en.wikipedia.org/wiki/Multi-divisional\\_form](https://en.wikipedia.org/wiki/Multi-divisional_form)

*Figure 12.7: Hierarchy of Function in an Organisation*

Clearly, this is just a *model*, it's not set in stone and decision making styles usually change from day-to-day and decision to decision. The same is not true in our software - *rules are rules*.

## 12.6 In Software Processes

It should be pretty clear that we are applying the Scale Invariance rule to Coordination Risk: all of the problems we've described as affecting teams, also affect software, although the scale and terrain are different. Software processes have limited *agency* - in most cases they follow fixed rules set down by the programmers, rather than self-organising like people can (so far).

As before, in order to face Coordination Risk in software, we need multiple agents all working together. Coordination Risks (such as race conditions or deadlock) only really occurs where *more than one thing is happening at a time*. This means we are considering *at least* multi-threaded software and anything above that (multiple CPUs, servers, data-centres and so on).

### CAP Theorem

The CAP Theorem<sup>27</sup> has a lot to say about Coordination Risk. Imagine talking to a distributed database, where your request (*read* or *write*) can be handled by one of many agents.

In the diagram below, we have just two agents 1 and 2, in order to keep things simple. User A *writes something* to the database, then User B *reads it back* afterwards.

According to the CAP Theorem, there are three properties we could desire in such a system:

- **Consistency:** Every read receives the most recent value from the last write.
- **Availability:** Every request receives a response.
- **Partition tolerance:** The system can operate despite the isolation (lack of communication with) some of its agents.

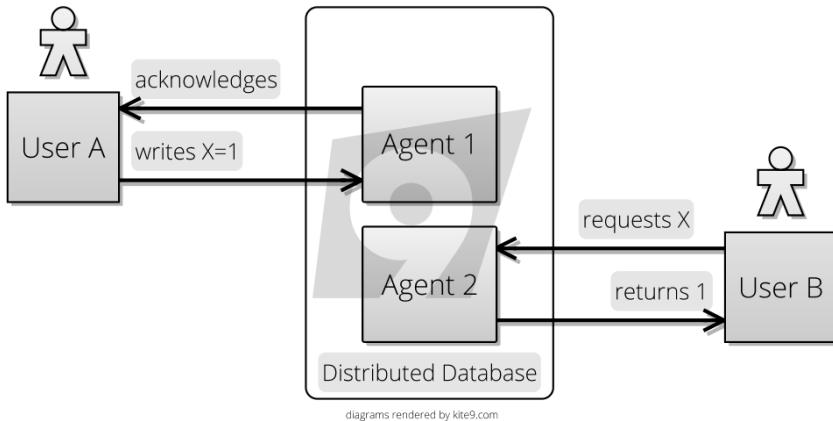

The CAP Theorem states that this is a Trilemma<sup>28</sup>. That is, you can only have two out of the three properties.

There are plenty of resources on the internet that discuss this in depth, but let's just illustrate with some diagrams to show how this plays out. In our

---

<sup>27</sup>[https://en.wikipedia.org/wiki/CAP\\_theorem](https://en.wikipedia.org/wiki/CAP_theorem)

<sup>28</sup><https://en.wikipedia.org/wiki/Trilemma>

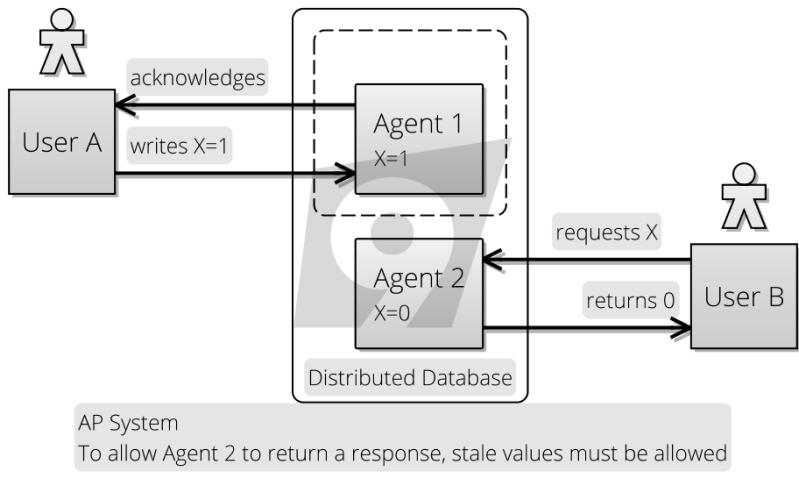

*Figure 12.8: User A and User B are both using a distributed database, managed by Agents 1 and 2, whom each have their own Internal Model*

diagram example, we'll say that *any* agent can receive the read or write. So this might be a GII decision making system, because all the agents are going to need to coordinate to figure out what the right value is to return for a read, and what the last value written was. In these, the last write (setting X to 1) was sent to Agent 1 which then becomes *isolated*, and can't be communicated with, due to network failure. What will User B get back?

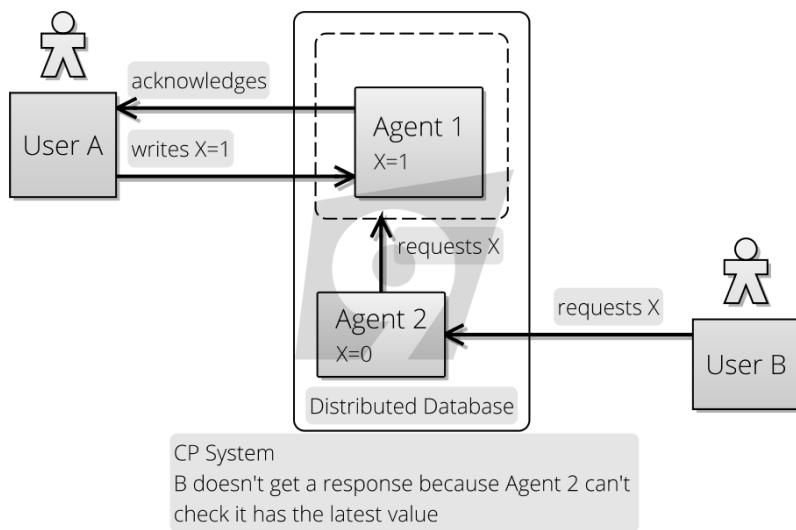

### With an AP System

With AP, you can see that User B is getting back a *stale value*. AP scenarios lead to Race Conditions: Agent 1's availability determines what value User B gets back.

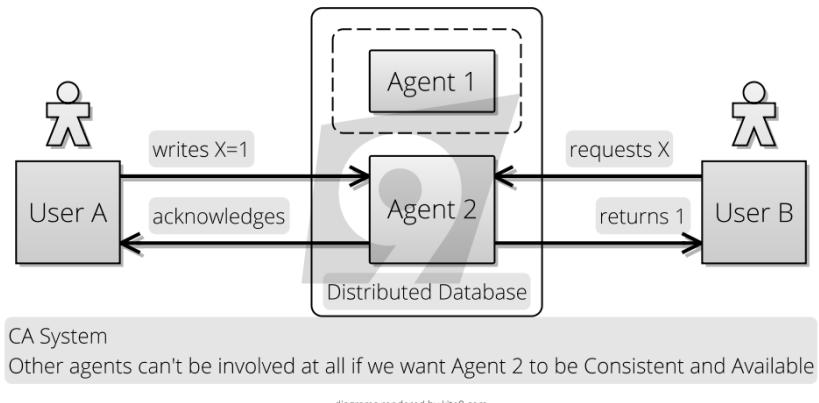

**Figure 12.9: In an AP system, the User B will get back a stale value for X**

### With an CP System

Where Agent 2 is left waiting for Agent 1 to re-appear, we are *blocked*. So CP systems lead to Deadlock scenarios.

*Figure 12.10: In an CA system, we can't have partition tolerance, so in order to be consistent a single Agent has to do all the work*

## With an CA System

Finally, if we have a CA system, we are essentially saying that *only one agent is doing the work*. (You can't partition a single agent, after all). But this leads to Resource Allocation and **Contention** around use of the scarce resource of Agent 2's attention. (Both Coordination Risk issues we met earlier.)

## Some Real-Life Examples

This sets an upper bound on Coordination Risk: we *can't* get rid of it completely in a software system, -or- a system on any other scale. Fundamentally, coordination problems are inescapable at some level. The best we can do is mitigate it by agreeing on protocols and doing lots of communication.

Let's look at some real-life examples of how this manifests in software.

## ZooKeeper

First, ZooKeeper<sup>29</sup> is an Open-Source datastore, which is used a lot for coordinating a distributed systems, and storing things like configuration information across them. If the configuration of a distributed system gets changed, it's important that *all of the agents in the system know about it*, otherwise... disaster.

<sup>29</sup><https://zookeeper.apache.org>

This *seems* trivial, but it quickly gets out-of-hand: what happens if only some of the agents receive the new information? What happens if a datacentre gets disconnected while the update is happening? There are lots of edge-cases.

ZooKeeper handles this by communicating inter-agent with its own protocol. It elects a **master agent** (via voting), turning it into an **AI**-style team. If the master is lost for some reason, a new leader is elected. *Writes* are then coordinated via the **master agent** who makes sure that a *majority of agents* have received and stored the configuration change before telling the user that the transaction is complete. Therefore, ZooKeeper is a CP system.

## Git

Second, git is a (mainly) write-only ledger of source changes. However, as we already discussed above, where different agents make incompatible changes, someone has to decide how to resolve the conflicts so that we have a single source of truth.

The Coordination Risk just *doesn't go away*.

Since multiple users can make all the changes they like locally, and merge them later, Git is an AP system: individual users may have *wildly* different ideas about what the source looks like until the merge is complete.

## Bitcoin

Finally, Bitcoin (BTC)<sup>30</sup> is a write-only distributed ledger<sup>31</sup>, where agents *compete* to mine BTC, but also at the same time record transactions on the ledger. BTC is also AP, in a similar way to Git. But new changes can only be appended if you have the latest version of the ledger. If you append to an out-of-date ledger, your work will be lost.

Because it's based on outright competition, if someone beats you to completing a mining task, then your work is wasted. So, there is *huge* Coordination Risk.

For this reason, BTC agents coordinate into mining consortia<sup>32</sup>, so they can avoid working on the same tasks at the same time. But this in itself is a problem, because the whole *point* of BTC is that it's competitive, and no one entity has control. So, mining pools tend to stop growing before they reach 50% of the BTC network's processing power. Taking control would

---

<sup>30</sup><https://en.wikipedia.org/wiki/Bitcoin>

<sup>31</sup>[https://en.wikipedia.org/wiki/Distributed\\_ledger](https://en.wikipedia.org/wiki/Distributed_ledger)

<sup>32</sup>[https://en.bitcoin.it/wiki/Comparison\\_of\\_mining\\_pools](https://en.bitcoin.it/wiki/Comparison_of_mining_pools)

be politically disastrous<sup>33</sup> and confidence in the currency (such as there is) would likely be lost.

## 12.7 Communication Is For Coordination

So, now we have a fundamental limit on how much Coordination Risk we can mitigate. And, just as there are plenty of ways to mitigate Coordination Risk within teams of people, organisations or living organisms, so it's the case in software.

Earlier in this chapter, we questioned whether Coordination Risk was just another type of Communication Risk. However, it should be clear after looking at the examples of competition, cellular life and Vroom and Yetton's Model that this is exactly *backwards*:

- Most single-celled life has no need for communication: it simply competes for the available resources. If it lacks anything it needs, it dies.
- There are *no* lines of communication on the UI decision-type. It's only when we want to avoid competition, by sharing resources and working towards common goals that we need to communicate.
- Therefore, the whole point of communication *is for coordination*.

In the next chapter, Map And Territory Risk, we're going to look at some new ways in which systems can fail, despite their attempts to coordinate.

---

<sup>33</sup>[https://www.reddit.com/r/Bitcoin/comments/5fe9vz/in\\_the\\_last\\_24hrs\\_three\\_mining\\_pools\\_have\\_control/](https://www.reddit.com/r/Bitcoin/comments/5fe9vz/in_the_last_24hrs_three_mining_pools_have_control/)

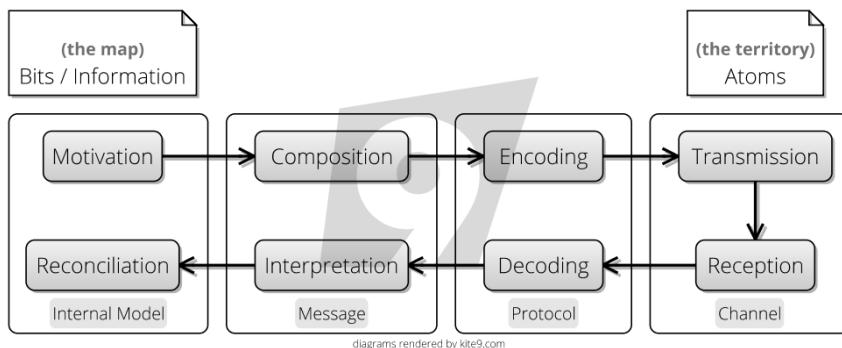

# Map And Territory Risk

As we discussed in the chapter on Abstraction, our understanding of the world is entirely informed by the names we give things and the abstractions we create.

(In the same way, **Risk-First** is about *identifying patterns* within software development and calling them out.)

Our Internal Models are a model of the world based on these patterns, and their relationships.

So there is a translation going on here: observations about the arrangement of *atoms* in the world get turned into patterns of *information* (measured in bits and bytes).

*Figure 13.1: Maps and Territories, and Communication happening between them*

Map And Territory Risk is the risk we face because we base our behaviour on our Internal Models rather than reality itself. It comes from the expression “Confusing the Map for the Territory”, attributed to Alfred Korzybski:

"Polish-American scientist and philosopher Alfred Korzybski remarked that "the map is not the territory" and that "the word is not the thing", encapsulating his view that an abstraction derived from something, or a reaction to it, is not the thing itself. Korzybski held that many people *do* confuse maps with territories, that is, confuse models of reality with reality itself." - Map-Territory Relation, *Wikipedia*<sup>1</sup>

In this chapter, we're going to make a case for analysing Map and Territory Risk along the same axes we introduced for Feature Risk, that is **Fitness**, **Audience** and **Evolution**. After that, we are going to widen the scope by looking at Map and Territory Risk within the context of **machines**, **people**, **hierarchies** and **markets**.

tbd - diagram of how our actions are based on the map, not the territory.

## 13.1 Fitness

In the picture shown here, from the Telegraph newspaper, the driver *trusted* the SatNav to such an extent that he didn't pay attention to the road-signs around him, and ended up getting stuck.

This wasn't borne of stupidity, but experience: SatNavs are pretty reliable. *So many times* the SatNav had been right, that the driver stopped *questioning its fallibility*.

So, there are two Map and Territory Risks here:

- The Internal Model of the *SatNav* contained information that was wrong: the track had been marked up as a road, rather than a path.
- The Internal Model of the *driver* was wrong: his abstraction of "the SatNav is always right" turned out to be only *mostly* accurate.

## 13.2 Internal Models as Dependencies, Features

What are the risks at play here? We've already looked in detail at the Dependency Risks involved in relying on something like a SatNav, in the Software Dependency Risk chapter. But here, we are really looking at the *Internal Models themselves* as a source of Dependency Risk too.

We could argue that the SatNav and the Driver's Internal Model had bugs in them. That is, they both suffer the Feature Implementation Risk we saw in

---

<sup>1</sup>[https://en.wikipedia.org/wiki/Mapterritory\\_relation](https://en.wikipedia.org/wiki/Mapterritory_relation)

A van got stuck on a narrow footpath when the driver took a wrong turn while blindly following his sat-nav. Photo: MEN

*Figure 13.2: Sat Nav Blunder Sends Asda Van Crashing Narrow Footpath - Telegraph Newspaper*

the Feature Risk chapter. If a SatNav has too much of this, you'd end up not trusting it, and getting a new one. With your *personal* Internal Model, you can't buy a new one, but you may learn to *trust certain abstractions less*, as this driver did.

In the Feature Risk chapter, we broke down Feature Risk on three axes: **Fitness, Evolution and Audience**.

Lets do this again and see how each type of Feature Risk can manifest in the Internal Model:

As with Features in a product, Information in an internal model has at least these three dimensions:

- **Fitness:** as discussed above with the SatNav example, this is how closely the information matches reality, and how *useful that is to us* (models that contain too much detail are as bad as models with too little).
- **Audience:** is all about how a piece of information is *shared* between many Internal Models, and it's this we are going to address further now.

Dimension	Feature Risk	Examples
Fit	 Fi Fit Risk	<ul style="list-style-type: none"> <li>• A filing cabinet containing too much junk.</li> <li>• Learning things that aren't useful.</li> <li>• Knowing how a car works, but actually needing to know how to drive.</li> <li>• Knowing how to program in one language, when another would be more appropriate.</li> <li>• Sat Nav had the wrong route.</li> <li>• Not quite remembering a recipe properly.</li> </ul>
Audience	 FD Feature Diff. Risk	<ul style="list-style-type: none"> <li>• Knowing outdated tools.</li> <li>• Writing last year's date on the cheque.</li> <li>• The bank sending letters to your old address.</li> <li>• Forgetting things</li> </ul>
Evolution	 R Regression Risk	<ul style="list-style-type: none"> <li>• Memes.</li> <li>• Demand for courses.</li> <li>• Metrics.</li> <li>• Echo Chambers</li> <li>• Shared values which exclude certain people.</li> <li>• Ideas going "out of fashion".</li> </ul>

Figure 13.3: Feature Risk, as manifested in the Internal Model

- **Evolution:** is all about how Internal Models change when they meet reality, and we'll cover that last.

### 13.3 Audience

We already know a lot about Internal Models and audience, as these have been the subject of previous chapters:

- We know from looking at Communication Risk that communication allows us to *share* information between Internal Models.
- We know from Coordination Risk the difficulties inherent in aligning Internal Models so that they cooperate.
- Job markets show us that there is demand for people with certain *skills*. This demonstrates to us that Market Risk is as applicable to Internal Models containing certain information as it is to products containing Features. This was the focus of the Ecosystem discussion in Boundary Risk.

... And, we're all familiar with *memes*:

"A meme acts as a unit for carrying cultural ideas, symbols, or practices, that can be transmitted from one mind to another through writing, speech, gestures, rituals, or other imitable phenomena with a mimicked theme." - Meme, *Wikipedia*<sup>2</sup>

Therefore, we should be able to track the rise-and-fall of *ideas* much as we can track stock prices. And in effect, this is what Google Trends<sup>3</sup> does. In the chart below, we can see the relative popularity of two search terms over time. This is probably as good an indicator as any of the audience for an abstraction at any point in time.

#### Example: Hype Cycles

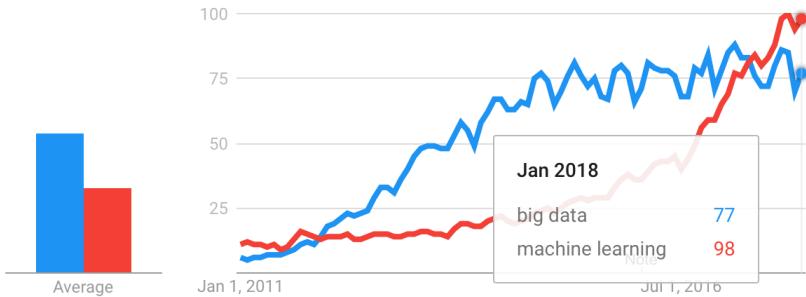

Most ideas (and most products) have a slow, hard climb to wide-scale adoption. But some ideas seem to disperse much more rapidly and are picked up quickly because they are exciting and promising, having greater "memetic potential" within society. One way this evolution manifests itself in the world is through the Hype Cycle<sup>4</sup>:

---

<sup>2</sup><https://en.wikipedia.org/wiki/Meme>

<sup>3</sup><https://trends.google.com>

<sup>4</sup>[https://en.wikipedia.org/wiki/Hype\\_cycle](https://en.wikipedia.org/wiki/Hype_cycle)

*Figure 13.4: Relative popularity of “Machine Learning” and “Big Data” as search terms on Google Trends, 2011-2018*

“The hype cycle is a branded graphical presentation developed and used by the American research, advisory and information technology firm Gartner, for representing the maturity, adoption and social application of specific technologies. The hype cycle provides a graphical and conceptual presentation of the maturity of emerging technologies through five phases.” - Hype Cycle, Wikipedia

The five phases (and the “Hype” itself) are shown in the chart below, with the thick black line being “Hype”:

Also in this diagram we are showing where the hype originates:

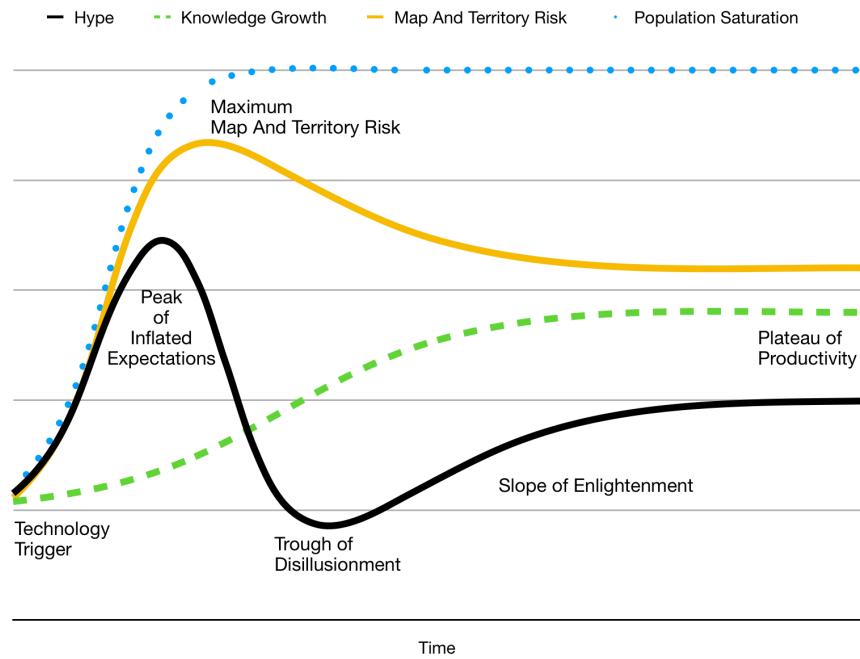

- The **saturation** of the idea within the audience (a dotted line).
- The **amount known** about the idea by the audience (a Learning Curve, if you will, a dashed line).

Both of these are modelled with Cumulative Distribution<sup>5</sup> curves. From these two things, we can figure out where our maximum Map and Territory Risk lies: it’s the point where awareness of an idea is furthest from the understanding of it. This acts as a “brake” on the **hype** around the idea, corresponding to the “Trough of Disillusionment”.

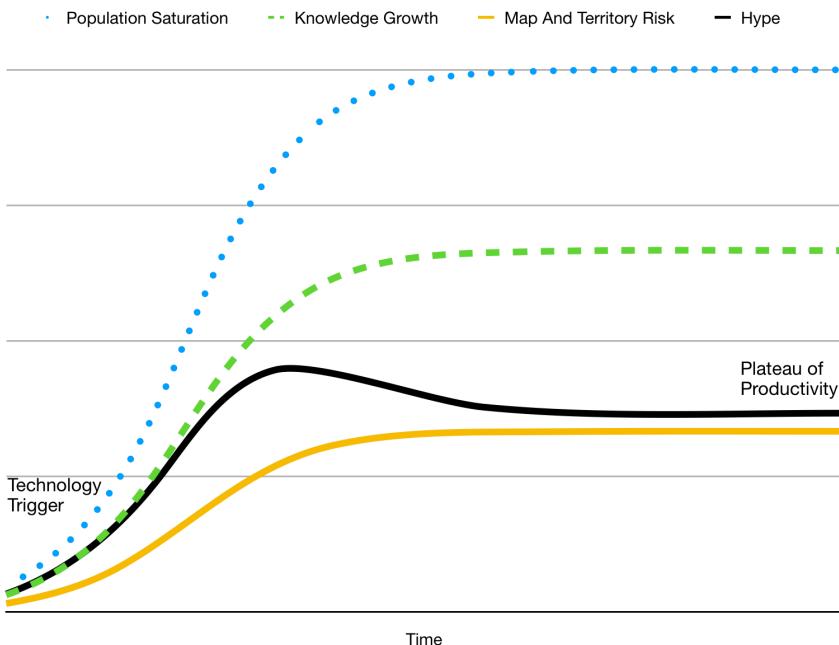

Where the **saturation** and **knowledge** grow together, there is no spike in Map and Territory Risk and we don’t see the corresponding “Trough of Disillusionment” at all, as shown in this chart:

---

<sup>5</sup>[https://en.wikipedia.org/wiki/Cumulative\\_distribution\\_function#Use\\_in\\_statistical\\_analysis](https://en.wikipedia.org/wiki/Cumulative_distribution_function#Use_in_statistical_analysis)

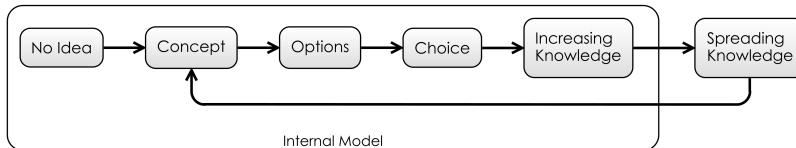

**Figure 13.5: Hype Cycle, along with Map & Territory Risk**

**Figure 13.6: Hype Cycle 2: Slower growth of Map and Territory Risk means no ‘Trough of Disillusionment’”**

## 13.4 Evolution

The chapter on Communication Risk introduced the following model for ideas:

*Figure 13.7: Spread of information between Internal Models*

But what happens next? As we saw in Boundary Risk, the **Peter Principle** applies, people will use dependencies up to the point when they start breaking down.

### Example: Metrics

Let's dive into a specific example now: someone finds a useful new metric that helps in evaluating performance.

It might be:

- **SLOC (Source Lines Of Code)**: i.e. the number of lines of code each developer writes per day/week whatever.
- **Function Points**: the number of function points a person on the team completes, each sprint.
- **Code Coverage**: the number of lines of code exercised by unit tests.
- **Response Time**: the time it takes to respond to an emergency call, say, or to go from a feature request to production.
- **Release cadence**: number of releases a team performs, per month, say.

With some skill, they may be able to *correlate* this metric against some other more abstract measure of success. For example:

“quality is correlated with more releases” “user-satisfaction is correlated with SLOC” “revenue is correlated with response time”

Because the *thing on the right* is easier to measure than the *thing on the left*, it becomes used as a proxy (or, Map) for the thing they are really interested in

(the Territory). At this point, it's *easy* to communicate this idea with the rest of the team, and *the market value of the idea is high*: it is a useful representation of reality, which is shown to be accurate at a particular point in time.

But *correlation* doesn't imply *causation*. The *cause* might be different:

- quality and number of releases might both be down to the simplicity of the product.
- user satisfaction and SLOC might both be down to the calibre of the developers.
- response time and revenue might both be down to clever team planning.

Metrics are seductive because they simplify reality and are easily communicated. But they *inherently* contain Map and Territory Risk: By relying *only* on the metrics, you're not really *seeing* the reality.

The devil is in the detail.

## Reality Evolves

In the case of metrics, this is where they start being used for more than just indicators, but as measures of performance or targets:

- If a team is *told* to do lots of releases, they will perform lots of releases *at the expense of something else*.
- If team members are promoted according to SLOC, they will make sure their code takes up as many lines as possible.
- In the UK, ambulances were asked to wait before admitting patients to Emergency wards, in order that hospitals could meet their targets<sup>6</sup>.

Some of this seems obvious: *Of course* SLOC is a terrible measure performance! We're not that stupid anymore. The problem is, it's not so much the *choice* of metric, but the fact that *all* metrics merely approximate reality with a few numbers. The map is *always* simpler than the territory, therefore there can be no perfect metrics.

In the same way that markets evolve to demand more features, our behaviour evolves to incorporate new ideas. The more popular an idea is, the more people will modify their behaviour as a result of it, and the more the world will change. Will the idea still be useful as the world adapts? Although the Hype Cycle model doesn't cover it, ideas and products all eventually have their day and decline in usefulness.

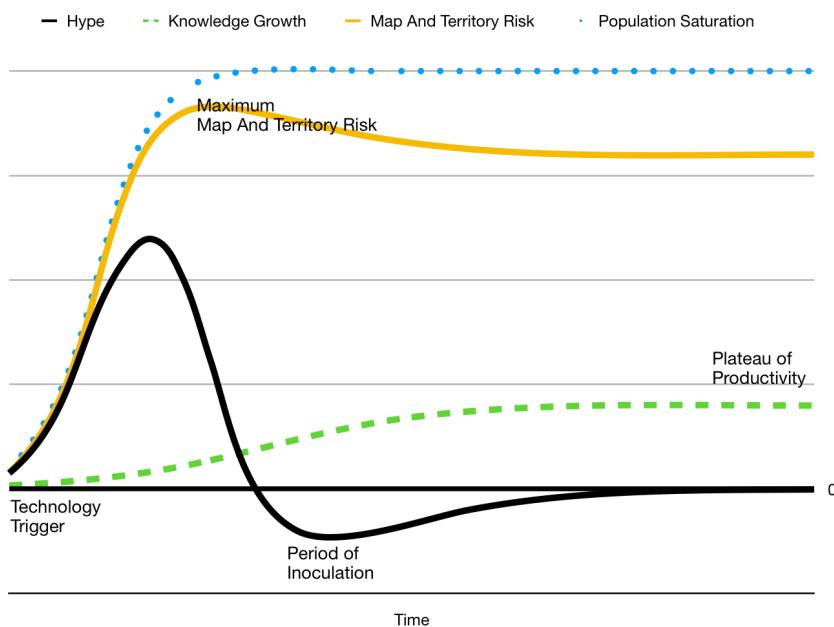

---

<sup>6</sup>[https://en.wikipedia.org/wiki/NHS\\_targets](https://en.wikipedia.org/wiki/NHS_targets)

## Bad Ideas

There are plenty of ideas which *seem a really good idea at the time* but then end up being terrible. It's only as we *learn about the products* and realize the hidden Map and Territory Risk that we stop using them. While SLOC is a minor offender, CFCs<sup>7</sup> or Leaded Petrol<sup>8</sup> are more significant examples.

The following Hyph Cycle chart shows an initially promising idea that turns out to be terrible, and there is a "Period of Inoculation" where the population realise their mistake. There is "negative hype" as they work to phase out the offending idea:

*Figure 13.8: Hype Cycle For Something that turns out to be a bad idea*

## 13.5 Humans and Machines

In the example of the SatNav, we saw how the *quality* of Map and Territory Risk is different for *people* and *machines*. Whereas people *should* be expected show skepticism to new (unlikely) information, our databases accept it unquestioningly. *Forgetting* is an everyday, usually benign part of our human

<sup>7</sup><https://en.wikipedia.org/wiki/Chlorofluorocarbon>

<sup>8</sup><https://en.wikipedia.org/wiki/Tetraethyllead>

Internal Model, but for software systems it is a production crisis involving 3am calls and backups.

For Humans, Map and Territory Risk is exacerbated by cognitive biases<sup>9</sup>:

“Cognitive biases are systematic patterns of deviation from norm or rationality in judgment, and are often studied in psychology and behavioral economics.” - Cognitive Bias, *Wikipedia*

There are *lots* of cognitive biases. But let’s just look at a couple that are relevant to Map and Territory Risk:

- **Availability Heuristic:** People overestimate the importance of knowledge they have been exposed to.
- **The Ostrich Effect:** Which is where dangerous information is ignored or avoided because of the emotions it will evoke.
- **Bandwagon Effect:** People like to believe things that other people believe. Could this be a factor in the existence of the Hype Cycle?

## 13.6 Hierarchical Organisations

Map And Territory Risk “trickles down” through an organisation. The higher levels have an outsize ability to pervert the incentives at lower levels because once an organisation begins to pursue a “bullshit objective”, the whole company can align to this.

The Huffington Post<sup>10</sup> paints a brilliant picture of how Volkswagen managed to get caught faking their emissions tests. As they point out:

“The leadership culture of VW probably amplified the problem by disconnecting itself from the values and trajectory of society, by entrenching in what another executive in the auto industry once called a “bullshit-castle”… No engineer wakes up in the morning and thinks: OK, today I want to build devices that deceive our customers and destroy our planet. Yet it happened. Why? Because of hubris at the top.” - Otto Scharmer, *Huffington Post*.

This article identifies the following process:

---

<sup>9</sup>[https://en.wikipedia.org/wiki/List\\_of\\_cognitive\\_biases](https://en.wikipedia.org/wiki/List_of_cognitive_biases)

<sup>10</sup>[https://www.huffingtonpost.com/otto-scharmer/the-fish-rots-from-the-he\\_b\\_8208652.html](https://www.huffingtonpost.com/otto-scharmer/the-fish-rots-from-the-he_b_8208652.html)

- **De-sensing:** VW Executives ignored *The Territory* society around them (such as the green movement), ensuring their maps were out of date. The top-down culture made it hard for reality to propagate back up the hierarchy.
- **Hubris/Absencing:** They pursued their own metrics of *volume* and *cost*, rather than seeking out others (a la the Availability Heuristic Bias). That is, focusing on their own *Map*, which is *easier* than checking the *Territory*. (See Hubris in the Agency Risk chapter).
- **Deception:** Backed into a corner, engineers had no choice but to find “creative” ways to meet the metrics.
- **Destruction:** Eventually, the truth comes out, to the detriment of the company, the environment and the shareholders. As the article’s title summarizes “A fish rots from the head down”.

## Personal Example

A similar (but less catastrophic) personal story from a bank I worked at, where the objectives end up being mis-aligned *within the company*:

1. My team had been tasked with building automated “smoke tests” of an application. But this was bullshit: We only needed to build these *at all* because the application was so complex. The reason it was so complex was...
2. The application was being designed within a “Framework” constructed by the department. However, the framework was only being used by this one application. Building a “reusable” framework which is only used by a single application is bullshit. But, we had to do this because...
3. The organisational structure was created along a “matrix”, with “business function” on one axis and “functional area” on another. Although we were only building the application for a single business function, it was expected to cater with all the requirements from the an entire “functional area”. This was bullshit too, because...
4. The matrix structure was largely the legacy of a recent merger with another department. As Conway’s Law predicts, our software therefore had to reflect this structure. But this was bullshit because...
5. The matrix structure didn’t represent reality in any useful way. It was designed to pacify the budget committee at the higher level, and try to demonstrate attributes such as *control* and *governance*. But this was bullshit too, because...

6. The budget that was given to our department was really based on how much fear the budget holders currently had of the market regulators. But this was bullshit too, because...
7. At a higher level, the executives had realised that our division wasn't one of the banks strategic strengths, and was working to close it all down anyway.

When faced with so many mis-aligned objectives, it seemed completely hopeless to concentrate on the task at hand. But then, a colleague was able to nihilistically add one final layer to this onion by saying:

8. "It's all about chasing money, which is bullshit, because life is bullshit."

## Picking Fights

It feels like there's no way back from that.

All of life might well be a big Map and Territory illusion. But let's analyse just a bit:

- At each layer, the objectives changed. But, they impacted on the objectives of the layer below.
- Therefore, it seems like the more layers you have, the less likely it is that your objectives become inconsistent between the lower and higher levels.
- On a new project, it seems like a good idea to model this stuff: does the objective of the work you're about to undertake "align" with the objectives at a higher level?

Trying to spot Map and Territory Risk ahead-of-time in this manner seems like a useful way of trying to avoid Vanity Projects, and, if you are good at it, allows you to see which Goals in the organisation are fragile and likely to change. However, usually, if you are working in a team, you have limited agency to decide which projects you feel are valuable.

This comes down to a personal decision: do you want to spend time working on projects that you know are going in the bin? Some developers have the attitude that, so long as they get paid, it doesn't matter. But others are in it for the satisfaction of the work itself, so this ends up being a personal call.

(This theme will be developed further in Staging and Classifying.)

## 13.7 Markets

So far, we've considered what happens to individuals, teams and organisations when told to optimise around a particular objective. In Coordination Risk we looked at how Communication was critical for Coordination to happen. And, as we've already discussed, Abstraction is a key part of communication.

The languages we adopt or create are *sets of useful abstractions* that allow us to communicate. But what happens when this goes wrong?

Inadequate Equilibria<sup>11</sup> by Eleizer Yudkovsky, looks at how perverse incentive mechanisms break not just departments, but entire societal systems. He highlights one example involving *academics* and *grantmakers* in academia:

- It's not very apparent which scientists are better than which other scientists.
- One proxy is what they've published (scientific papers) and where they've published (journals).
- Universities want to attract research grants, and the best way to do this is to have the best scientists.
- Because "best" isn't measureable, they use the proxy.
- Therefore, immense power rests in the hands of the journals, since they can control the money-proxy.
- Therefore, journals are able to charge large amounts of money to universities for subscriptions.

"Now consider the system of scientific journals... Some journals are prestigious. So university hiring committees pay the most attention to publications in that journal. So people with the best, most interesting-looking publications try to send them to that journal. So if a university hiring committee paid an equal amount of attention to publications in lower-prestige journals, they'd end up granting tenure to less prestigious people. Thus, the whole system is a stable equilibrium that nobody can unilaterally defy except at cost to themselves." - Inadequate Equilibria, Eleizer Yudkovsky<sup>12</sup>

As the book points out, while everyone *persists* in using an inadequate abstraction, the system is broken. However, Coordination would be required

---

<sup>11</sup><https://equilibriabook.com>

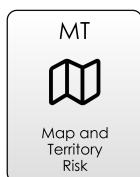

<sup>12</sup><https://equilibriabook.com/molochs-toolbox/>

for everyone to *stop* doing it this way, which is hard work. (At least within a hierarchy, Maps can get fixed.)

This is a *small example* from a much larger, closely argued book, and it's worth taking the time to read a couple of the chapters on this interesting topic.

As usual, this chapter forms a grab-bag of examples in a complex topic. But it's time to move on as there is one last stop we have to make on the Risk Landscape, and that is to look at Operational Risk.

(NB: The Hype Cycle model is available in **Numbers** form here<sup>13</sup>.)

- Risks due to the differences between reality and the internal model of reality, and the assumption that they are equivalent.

*Figure 13.9: Map And Territory Risk*

(talk about how operational risk is an extension of this). tbd

---

<sup>13</sup><https://github.com/risk-first/website/blob/master/RiskMatrix.numbers>

# Staging And Classifying

Our tour is complete.

We've collected on this journey around the Risk Landscape a (hopefully) good, representative sample of Risks and where to find them. But if we are good collectors, then before we're done we should Stage our collection on some solid [Mounting Boards], and do some work in classifying what we've seen.

tbd collecting image

If you've been reading closely, you'll notice that a number of themes come up again and again within the different chapters. For example, concepts like **Fit, Abstraction, Evolution**. Although we've been looking at patterns of risk across software projects, it's time to look at the *patterns within the patterns*.

## 14.1 First, A Recap

tbd. list of risks, broken down

## 14.2 Some Observations

### 1. The Power Of Abstractions

Abstraction appears as a concept continually throughout the book, whether we are looking at Communication, Complexity Metrics, Map and Territory Risk or how it causes Boundary Risk. And, so far, we've looked at some complicated examples of abstractions, such as network protocols, dependencies on technology or Business Processes.

There's a good reason for this repetition. Abstraction is at the heart of *everything we do within software*. So, let's now *generalize* what is happening with abstraction, but have in mind *a really simple example*: giving a name to something.

### Inventing an Abstraction means:

- **Creating a Feature.** So, at the simplest end, you might be simply *naming a pattern* of behaviour we see in the real world, such as "Binge Watching" or "Remote Working", or naming your dog, "Alfie". These abstractions are Features in the sense that other people can choose to use them, if they fit their requirements.
- **Creating a Boundary.** By naming something, you *implicitly* create a boundary, because the world is now divided into "things which *are X*" and "things which *are not X*". Sometimes, this abstraction may literally end up having a physical boundary to enforce this division (such as, "My Property / Not My Property"). *Boundary Risk is created by abstractions*.
- **Creating a Protocol.** At the very simplest level (again), this is just introducing *new words to a language*. Therefore, we create Protocol Risk: what if the person we are communicating with *\_doesn't know this word?*
- **Increasing Complexity.** Because, the more words we have, the more complex the language is.

tbd, diagram.

### Choosing an Abstraction means:

- **Overcoming a Learning Curve:** Because you have to *learn* a name in order to use it (whether a function, a dog, or the name of someone at a party).
- **Accepting Boundary Risks.** Just using *a single word* means accepting the whole *ecosystem* of the language the word is in. Using *french words* means the Boundary Risk of the French Language.
- **Accepting Map And Territory Risk.** Because the word refers to the *concept* of the thing, and *not the thing itself*.

tbd. diagram

### Depending On an Abstraction means:

- **Living with Dependency Risk:** We depend on a word in our language, or a function in our library, or a service on the internet. But all of these things are *unreliable*. The word might not communicate what you want it to, or be understood by the audience, the function might not work, the service might be down.
- **Accepting Evolution.** That language *changes* and *evolves*, and the words you are using now might not always mean what you want them to mean. Software too changes and evolves. We've seen this in Red Queen Risk, Feature Drift Risk, Regression Risk and Protocol Risk.
- **Accepting Coordination Risk.** Where a Dependency has Agency, we need to consider how to work with it.

tbd diagram.

## 2. Your Feature Risk is Someone Else's Dependency Risk

In the Feature Risk chapter, we looked at the problems of *supplying a dependency to someone else*: you've got to satisfy a demand Market Risk, and ensure a close fit with requirements Conceptual Integrity Risk. The chapter on Production Risk went further, looking at specific aspects of being the supplier of an IT service as a dependency.

However, over the rest of the Dependency Risk chapters, we looked at this from the point of view of *being a client to someone else*: you want to find trustworthy, reliable dependencies that don't give up when you least want them to.

So Feature Risk *is* Dependency Risk: they're *two sides of the same coin*. You face Dependency Risk when you're a client, Feature Risk when you're the supplier.

We've looked at three dimensions of Feature Risk: - Fit - Evolution - Audience (recap this)

Dependency Risk has three dimensions too:

- Schedule (things happening in time, running out of stuff. e.g I need enough money to get this done, etc. I need enough patience, enough loyalty, trust, entente.)
- Technology (depending on software, hardware, etc. )
- Organisation (arrangements of people, processes, product)

- Agency (people/machines/processes/organisations doing what you asked, working with you)
- 

Using a dependency requires learning a *protocol*. You have to learn to use it. Maybe it learns you. This requires changes to your internal model.

Internal Model - Communication – Dependency Goal

### 3. Coordination Risk As Eden

- similar to \_threading/deadlocking issues
- Coordination is how you deal with abstractions. and this means communication.

tbd diagram: abstractions -> agency -> coordination -> communication

One thing that should be apparent is that there are similarities in the risks between all the kinds of

- draw a diagram of this system. mark on all the different risks using numbers. mention specifically that since this is a diagram, it is a “map”.

## 14.3 Towards A Periodic Table Of Risks

tbd, diagram, explanatory text.

## 14.4 Patterns

As we said at the start, Risk-First is all about developing *A Pattern Language*. We can use the terms like “*Feature Risk*” or “*Learning Curve Risk*” to explain phenomena we see on software projects. If we want to De-Risk our work, we need to be able to explain what the risks are, and what we expect to do about them.

So, lastly in part 2 let’s put our language to work, and look at some past project failures. Can we apply our lexicon to them?

On to Stories Of Failure.
