Preface

Welcome to Risk-First!

Let's cover some of the big questions up-front: The why, what, who, how and where of *The Menagerie*.

Why

Scrum, Waterfall, Lean, Prince2: what do they all have in common?

I've started this because, on my career journey, I've noticed that the way I do things doesn't seem to match up with the way the books *say* it should be done. And, I found this odd and wanted to explore it further. Hopefully, you, the reader, will find something of use in this.

I started with this observation: *Development Teams* put a lot of faith in methodology. Sometimes, this faith is often so strong it borders on religion. (Which in itself is a concern.) For some, this is Prince2.

Developers put a lot of faith in *particular tools* too. Some developers are pro-or-anti-Java, others are pro-or-anti-XML. All of them have their views coloured by their *experiences* (or lack of) with these tools. Was this because their past projects *succeeded* or *failed* because of them?

As time went by, I came to see that the choice of methodology, process or tool was contingent on the problem being solved, and the person solving the problem. We don't face a shortage of tools in IT, or a shortage of methodologies, or a shortage of practices. Essentially, that all the tools and methodologies that the industry had supplied were there to help *minimize the risk of my project failing*.

This book considers that perspective: that building software is all about *managing risk*, and that these methodologies are acknowledgements of this

fact, and they differ because they have *different ideas* about which are the most important *risks to manage*.

What This Is

Hopefully, after reading this, you'll come away with:

- An appreciation of how risk underpins everything we do as developers, whether we want it to or not.
- A framework for evaluating methodologies, tools and practices and choosing the right one for the task-at-hand.
- A recontextualization of the software process as being an exercise in mitigating different kinds of risk.
- The tools to help you decide when a methodology or tool is *letting you down*, and the vocabulary to argue for when it's a good idea to deviate from it.

This is not intended to be a rigorously scientific work: I don't believe it's possible to objectively analyze a field like software development in any meaningful, statistically significant way. (For one, things just change too fast)

"I have this Pattern"

—Attributed to Ward Cunningham, *Have This Pattern, C2 Wiki*¹

Does that diminish it? If you have visited the TVTropes² website, you'll know that it's a set of web-pages describing *common patterns* of narrative, production, character design etc. to do with fiction. For example:

"Sometimes, at the end of a Dream Sequence or an All Just a Dream episode, after the character in question has woken up and demonstrated any [lesson] that the dream might have been communicating, there's some small hint that it wasn't a dream after all, even though it quite obviously was... right?"

—Or Was It a Dream?, *TVTropes*³

²<https://tvtropes.org>

³<https://tvtropes.org/pmwiki/pmwiki.php/Main/OrWasItADream>

Is it scientific? No. Is it correct? Almost certainly. TVTropes is a set of *empirical patterns* for how stories on TV and other media work. It's really useful, and a lot of fun. (Warning: it's also incredibly addictive).

In the same way, “Design Patterns: Elements of Reusable Object-Oriented Software⁴”, is a book detailing patterns of *structure* within Object-Oriented programming, such as:

“[The] Adapter [pattern] allows classes with incompatible interfaces to work together by wrapping its own interface around that of an already existing class...”

—Design Patterns, Wikipedia⁵

Patterns For Practitioners

Design Patterns aimed to be a set of *useful* patterns which practitioners could use in their software to achieve certain goals. “I have this pattern” was a phrase used to describe how they had seen a certain set of constraints before, and how they had solved it in software.

This book was a set of experts handing down their battle-tested practices for other developers to use, and, whether you like patterns or not, knowing them is an important part of being a software developer, as you will see them used everywhere you go and probably use them yourself.

In the same way, Risk-First aims to be a set of *Patterns for Software Risk*. Hopefully after reading this book, you will see where risk hides in software projects, and have a name for it when you see it.

Towards a “Periodic Table”

In the latter chapters of “The Menagerie” we try to assemble these risk patterns into a cohesive whole. Projects fail because of risks, and risks arise from predictable sources.

What This is Not

This is not intended to be a rigorously scientific work: I don't believe it's possible to objectively analyze a field like software development in any meaningful, statistically significant way. (For one, things just change too fast

⁴<http://amzn.eu/d/3c0wTkH>

⁵https://en.wikipedia.org/wiki/Design_Patterns

Neither is this site isn't going to be an exhaustive guide of every possible software development practice and methodology. That would just be too long and tedious.

Neither is this really a practitioner's guide to using any particular methodology: If you've come here to learn the best way to do Retrospectives, then you're in the wrong place. There are plenty of places you can find that information already. Where possible, this site will link to or reference concepts on Wikipedia or the wider internet for further reading on each subject.

Who

This work is intended to be read by people who work on software projects, and especially those who are involved in managing software projects.

If you work collaboratively with other people in a software process, you should find Risk-First a useful lexicon of terms to help describe the risks you face.

But here's a warning: This is going to be a depressing book to read. It is book one of a two-book series, but in **Book One** you only get to meet the bad guy.

While **Book Two** is all about *how to succeed*, This book is all about how projects *fail*. In it, we're going to try and put together a framework for understanding the risk of failure, in order that we can reconstruct our understanding of our activities on a project based on avoiding it.

So, if you are interested in *avoiding your project failing*, this is probably going to be useful knowledge.

For Developers

Risk-First is a tool you can deploy to immediately improve your ability to plan your work.

Frequently, as developers we find software methodologies "done to us" from above. Risk-First is a toolkit to help *take apart* methodologies like Scrum, and understand them. Methodologies are *bicycles*, rather than *religions*. Rather than simply *believing*, we can take them apart and see how they work.

For Project Managers and Team Leads

All too often, Project Managers don't have a full grasp of the technical details of their projects. And this is perfectly normal, as the specialization belongs below them. However, projects fail because risks materialize, and risks materialize because the devil is in those details.

This seems like a lost cause, but there is hope: the ways in which risks materialize on technical projects is the same every time. With Risk-First we are attempting to name each of these types of risk, which allows for a dialog with developers about which risks they face, and the order they should be tackled.

Risk-First allows a project manager to pry open the black box of development and talk with developers about their work, and how it will affect the project. It is another tool in the (limited) arsenal of techniques a project manager can bring to bear on the task of delivering a successful project.

How

One of the original proponents of the Agile Manifesto by stating:

“It’s all about risk”

—Kent Beck, *Extreme Programming Explained*⁶

This is a promising start. From there, he introduces his methodology, Extreme Programming, there is no clear model of software risk underpinning the work, and the relationship between the practices he espouses and the risks he is avoiding are hidden.

In this book, we are going to introduce a model of software project risk. This means that in **Book Two** (Risk-First: Tools and Practices), we can properly analyse Extreme Programming and *understand* what drives them. Since they are designed to deliver successful software projects, they must be about mitigate risks, and we will uncover *exactly which risks are mitigated and how they do it*.

On to The Executive Summary

Executive Summary

1. There are Lots of Ways of Running Software Projects

There are lots of different ways to look at a project. For example, metrics such as “number of open tickets”, “story points”, “code coverage” or “release cadence” give us a numerical feel for how things are going and what needs to happen next. We also judge the health of projects by the practices used on them - Continuous Integration, for example.

Software methodologies, then, are collections of tools and practices: “Agile”, “Waterfall”, “Lean” or “Phased Delivery” (for example) all suggest different approaches to running a project, and are opinionated about the way they think projects should be done and the tools that should be used.

None of these is necessarily more “right” than another- they are suitable on different projects at different times.

A key question then is: **how do we select the right tools for the job?**

2. We can Look at Projects in Terms of Risks

One way to examine a project in-flight is by looking at the risks it faces.

Commonly, tools such as RAID logs and RAG status reporting are used. These techniques should be familiar to project managers and developers everywhere.

However, the Risk-First view is that we can go much further: that each item of work being done on the project is mitigating a particular risk. Risk isn’t something that just appears in a report, it actually drives *everything we do*.

For example:

- A story about improving the user login screen can be seen as reducing *the risk of users not signing up*.

- A task about improving the health indicators could be seen as mitigating *the risk of the application failing and no-one reacting to it*.
- Even a task as basic as implementing a new function in the application is mitigating *the risk that users are dissatisfied and go elsewhere*.

One assertion of Risk-First therefore, is that every action you take on a project is to mitigate some risk.

3. We Can Break Down Risks on a Project Methodically

Although risk is usually complicated and messy, other industries have found value in breaking down the types of risks that affect them and addressing them individually.

For example:

- In manufacturing, *tolerances* allow for calculating the likelihood of defects in production.
- In finance, reserves are commonly set aside for the risks of stock-market crashes, and teams are structured around monitoring these different risks.
- The insurance industry is founded on identifying particular risks and providing financial safety-nets for when they occur, such as death, injury, accident and so on.

Software risks are difficult to quantify, and mostly, the effort involved in doing so *exactly* would outweigh the benefit. Nevertheless, there is value in spending time building *classifications of risk for software*. That's what Risk-First does: describes the set of *risk patterns* we see every day on software projects.

With this in place, we can:

- Talk about the types of risks we face on our projects, using an appropriate language.
- Expose Hidden Risks that we hadn't considered before.
- Weigh the risks against each other, and decide which order to tackle them.

4. We Can Analyse Tools and Techniques in Terms of how they Mitigate Risk

If we accept the assertion above that *all* the actions we take on a project are about mitigating risks, then it stands to reason that the tools and techniques available to us on a project are there for mitigating different types of risks.

For example:

- If we do a Code Review of knowledge not being widely-enough shared.
- If we write Unit Tests, we're also mitigating the risk of bugs going to production, but we're also mitigating against future changes breaking our existing functionality.
- If we enter into a contract with a supplier, we are mitigating the risk of the supplier vanishing and leaving us exposed. With the contract in place, we have legal recourse against this risk.

Different tools are appropriate for mitigating different types of risks.

5. Different Methodologies for Different Risk Profiles

In the same way that our tools and techniques are appropriate to dealing with different risks, the same is true of the methodologies we use on our projects. We can use a Risk-First approach to examine the different methodologies, and see which risks they address.

For example:

- **Agile** methodologies prioritise mitigating the risk that requirements capture is complicated, error-prone and that requirements change easily.
- **Waterfall** takes the view that coding effort is an expensive risk, and that we should build plans up-front to avoid it.
- **Lean** takes the view that risk lies in incomplete work and wasted work, and aims to minimize that.

Although many developers have a methodology-of-choice, the argument here is that there are tradeoffs with all of these choices. Methodologies are like *bicycles*, rather than *religions*. Rather than simply *believing*, we can take them apart and see how they work.

We can place methodologies within a framework, and show how choice of methodology is contingent on the risks faced.

6. Driving Development With a Risk-First Perspective

We have described a model of risk within software projects, looking something like this:

Figure 1: Methodologies, Risks, Practices

How do we take this further?

The first idea we explore is that of the Risk Landscape where the risks on the project are more favourable than where they started.

From there, we examine basic risk archetypes you will encounter on the software project, to build up a Taxonomy of Software Risk, and look at which specific tools you can use to mitigate each kind of risk.

Then, we look at different software practices, and how they mitigate various risks. Beyond this we examine the question: *how can a Risk-First approach inform the use of this technique?*

For example:

- If we are introducing a **Sign-Off** in our process, we have to balance the risks it *mitigates* (coordination of effort, quality control, information sharing) with the risks it *introduces* (delays and process bottlenecks).
- If we have **Redundant Systems**, this mitigates the risk of a *single point of failure*, but introduces risks around *synchronizing data* and *communication* between the systems.
- If we introduce **Process**, this may make it easier to *coordinate as a team* and *measure performance* but may lead to bureaucracy, focusing on the wrong goals or over-rigid interfaces to those processes.

Risk-First aims to provide a framework in which we can *analyse these choices* and weigh up *accepting* versus *mitigating* risks.

Part I

Introduction

A Simple Scenario

First up, I'm going to introduce a simple model for thinking about risk.

1.1 A Simple Scenario

Lets for a moment forget about software completely, and think about *any endeavor at all* in life. It could be passing a test, mowing the lawn or going on holiday. Choose something now. I'll discuss from the point of view of "cooking a meal for some friends", but you can play along with your own example.

Goal In Mind

Now, in this endeavour, we want to be successful. That is to say, we have a Goal In Mind we *probably* have to do some tasks.

Since our goal only exists *in our head*, we can say it is part of our Internal Model of the world. That is, the model we have of reality. This model extends to *predicting what will happen*.

If we do nothing, our friends will turn up and maybe there's nothing in the house for them to eat. Or maybe, the thing that you're going to cook is going to take hours and they'll have to sit around and wait for you to cook it and they'll leave before it's ready. Maybe you'll be some ingredients short, or maybe you're not confident of the steps to prepare the meal and you're worried about messing it all up.

Attendant Risk

These *nagging doubts* that are going through your head I'll call the Attendant Risks: they're the ones that will occur to you as you start to think about what

will happen.

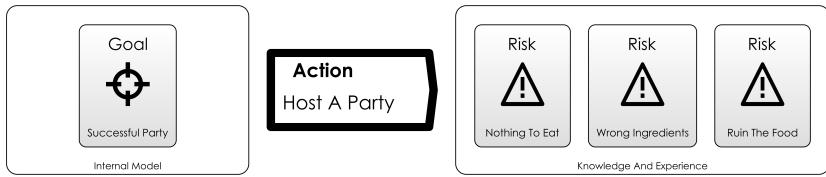

Figure 1.1: Goal In Mind, with the risks you know about

When we go about preparing this wonderful evening, we can deal with these risks and try to mitigate them: shop for the ingredients in advance, prepare parts of the meal, maybe practice the cooking in advance. Or, we can wing it, and sometimes we'll get lucky.

How much effort we expend on mitigating Attendant Risks.

Hidden Risks

There are also hidden Attendant Risks¹ that you might not know about: if you're poaching eggs for dinner, you might know that fresh eggs poach best. These are the "Unknown Unknowns" of Rumsfeld's model².

Figure 1.2: Goal In Mind, the risks you know about and the ones you don't

Different people will evaluate the risks differently. (That is, worry about them more or less.) They'll also *know* about different risks. They might have cooked the recipe before, or organised lots more dinner parties than you.

How we evaluate the risks, and which ones we know about depends on our **knowledge** and **experience**, then. And that varies from person to person (or team to team). Lets call this our Internal Model.

¹Glossary#attendant-risk

²https://en.wikipedia.org/wiki/There_are_known_unknowns

Model Meets Reality

As the dinner party gets closer, we make our preparations, and the inadequacies of the Internal Model reveal themselves; while other things we were worried about may not materialise, things we thought would be minor risks turn out to be greater.

Our model is forced into contact with reality, and the model changes. We may be forced to take further, mitigating actions to deal with these new risks, as shown in this diagram.

Figure 1.3: How taking action affects Reality, and also changes your internal model

If we had a good model, and took the right actions, we should see positive outcomes. If we failed to mitigate risks, or took inappropriate actions, we'll probably see negative outcomes.

1.2 On To Software

In this website, we're going to look at the risks in the software process and how these are mitigated by the various methodologies you can choose from.

Let's examine the scenario of a new software project, and expand on the simple model being outlined above: instead of a single person, we are likely to have a team, and our model will not just exist in our heads, but in the code we write.

On to Development Process

Development Process

In the previous chapter we looked at a simple model for risks on any given activity.

Now, let's look at the everyday process of developing *a new feature* on a software project, and see how our risk model informs it.

2.1 An Example Process

Let's ignore for now the specifics of what methodology is being used - we'll come to that later. Let's say your team have settled for a process something like the following:

1. **Specification:** A new feature is requested somehow, and a business analyst works to specify it.
2. **Code And Unit Test:** A developer writes some code, and some unit tests.
3. **Integration:** They integrate their code into the code base.
4. **UAT:** They put the code into a User Acceptance Test (UAT) environment, and user(s) test it.

... All being well, the code is released to production.

Now, it might be waterfall, it might be agile, we're not going to commit to specifics at this stage. It's probably not perfect, but let's just assume that *it works for this project* and everyone is reasonably happy with it.

I'm not saying this is the *right* process, or even a *good* process: you could add code review, a pilot, integration testing, whatever. We're just doing some analysis of *what process gives us*.

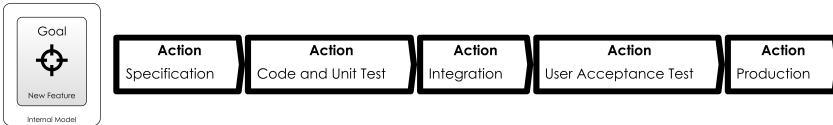

Figure 2.1: A Simple Development Process

What's happening here? Why these steps?

2.2 Minimizing Risks - Overview

I am going to argue that this entire process is *informed by software risk*:

1. We have *a business analyst* who talks to users and fleshes out the details of the feature properly. This is to minimize the risk of **building the wrong thing**.
2. We *write unit tests* to minimize the risk that our code **isn't doing what we expected, and that it matches the specifications**.
3. We *integrate our code* to minimize the risk that it's **inconsistent with the other, existing code on the project**.
4. We have *acceptance testing* and quality gates generally to **minimize the risk of breaking production**, somehow.

We could skip all those steps above and just do this:

1. Developer gets wind of new idea from user, logs onto production and changes some code directly.

We can all see this would be a disaster, but why?

Two reasons:

1. You're meeting reality all-in-one-go: all of these risks materialize at the same time, and you have to deal with them all at once.
2. Because of this, at the point you put code into the hands of your users, your Internal Model now need to be dealt with at the same time, in production.

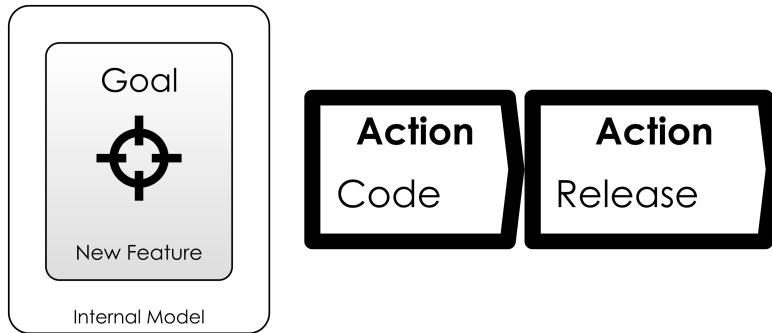

Figure 2.2: A Dangerous Development Process

2.3 Applying the Model

Let's look at how our process should act to prevent these risks materializing by considering an unhappy path, one where at the outset, we have lots of Hidden Risks ready to materialize. Let's say a particularly vocal user rings up someone in the office and asks for new **Feature X** to be added to the software. It's logged as a new feature request, but:

- Unfortunately, this feature once programmed will break an existing **Feature Y**.
- Implementing the feature will use some api in a library, which contains bugs and have to be coded around.
- It's going to get misunderstood by the developer too, who is new on the project and doesn't understand how the software is used.
- Actually, this functionality is mainly served by **Feature Z**...
- which is already there but hard to find.

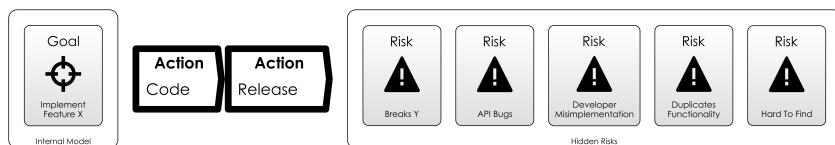

Figure 2.3: Development Process - Hidden Risks

This is a slightly contrived example, as you'll see. But let's follow our feature through the process and see how it meets reality slowly, and the hidden risks are discovered:

Specification

The first stage of the journey for the feature is that it meets the Business Analyst (BA). The *purpose* of the BA is to examine new goals for the project and try to integrate them with *reality as they understands it*. A good BA might take a feature request and vet it against the internal logic of the project, saying something like:

- "This feature doesn't belong on the User screen, it belongs on the New Account screen"
- "90% of this functionality is already present in the Document Merge Process"
- "We need a control on the form that allows the user to select between Internal and External projects"

In the process of doing this, the BA is turning the simple feature request *idea* into a more consistent, well-explained *specification* or *requirement* which the developer can pick up. But why is this a useful step in our simple methodology? From the perspective of our Internal Model, we can say that the BA is responsible for:

- Trying to surface Hidden Risks
- Trying to evaluate Attendant Risk and make it clear to everyone on the project.

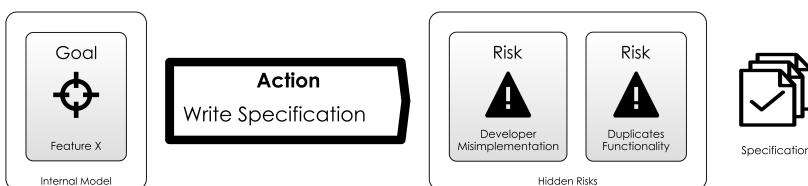

Figure 2.4: BA Specification: exposing hidden risks as soon as possible

In surfacing these risks, there is another outcome: while **Feature X** might be flawed as originally presented, the BA can "evolve" it into a specification,

and tie it down sufficiently to reduce the risks. The BA does all this by simply *thinking about it, talking to people and writing stuff down*.

This process of evolving the feature request into a requirement is the BAs job. From our Risk-First perspective, it is *taking an idea and making it meet reality*. Not the *full reality* of production (yet), but something more limited.

Code And Unit Test

The next stage for our feature, **Feature X** is that it gets coded and some tests get written. Let's look at how our goal in mind meets a new reality: this time it's the reality of a pre-existing codebase, which has its own internal logic.

As the developer begins coding the feature in the software, she will start with an Internal Model of the software, and how the code fits into it. But, in the process of implementing it, she is likely to learn about the codebase, and her Internal Model will develop.

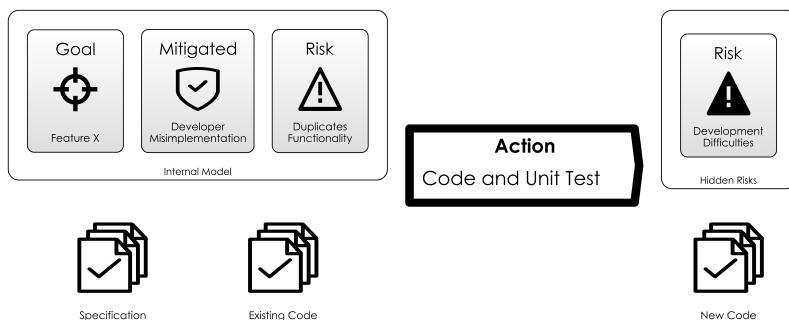

Figure 2.5: Coding Process: exposing more hidden risks as you code

A couple of things about this diagram:

- In boxes, we are showing Risks, whereas:
- Beneath them, we are showing actual *physical artifacts* which exist in the real world.
- *Actions* might *meet reality*, but they are *changing reality* too, by producing these artifacts.

Integration

Integration is where we run *all* the tests on the project, and compile *all* the code in a clean environment: the “*reality*” of the development environment

can vary from one developer's machine to another.

So, this stage is about the developer's committed code meeting a new reality: the clean build.

At this stage, we might discover the Hidden Risk that we'd break **Feature Y**

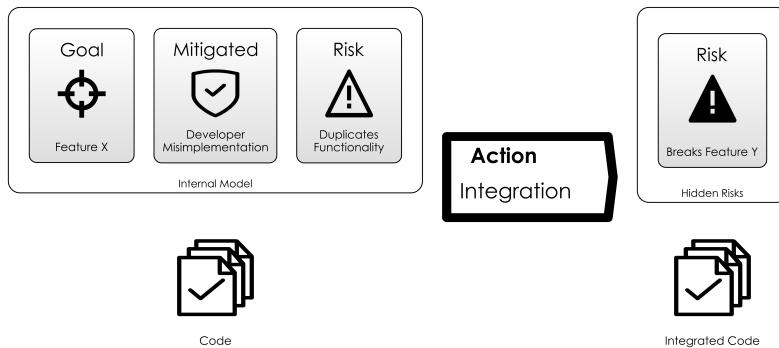

Figure 2.6: Integration testing exposes hidden risks before you get to production

User Acceptance Test

Is where our feature meets another reality: *actual users*. I think you can see how the process works by now. We're just flushing out yet more Hidden Risks:

- Taking Action is the *only* way to create change in the world.
- It's also the only way we can *learn* about the world, adding to our Internal Model. In this case, we discover the user's difficulty in finding the feature.

2.4 Observations

A couple of things:

First, the people setting up the development process *didn't know* about these *exact* risks, but they knew the *shape that the risks take*. The process builds "nets" for the different kinds of hidden risks without knowing exactly what they are. Part of the purpose of this site is to help with this and try and provide a taxonomy for different types of risks.

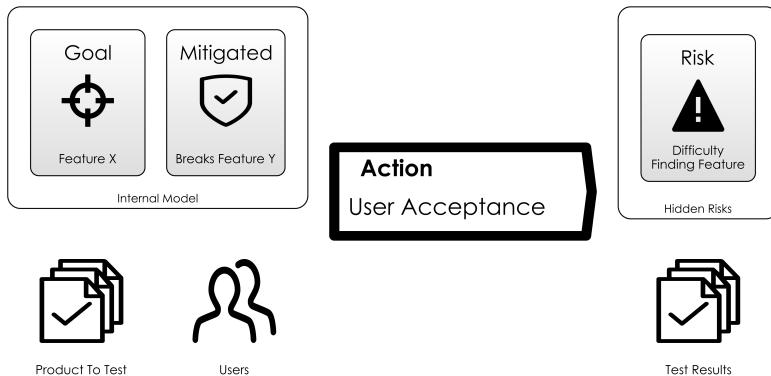

Figure 2.7: UAT - putting tame users in front of your software is better than real ones, where the risk is higher

Second, are these really risks, or are they *problems we just didn't know about?* I am using the terms interchangeably, to a certain extent. Even when you know you have a problem, it's still a risk to your deadline until it's solved. So, when does a risk become a problem? Is a problem still just a schedule-risk, or cost-risk? It's pretty hard to draw a line and say exactly.

Third, the real take-away from this is that all these risks exist because we don't know 100% how reality is. Risk exists because we don't (and can't) have a perfect view of the universe and how it'll develop. Reality is reality, *the risks just exist in our head*.

Fourth, hopefully you can see from the above that really *all this work is risk management, and all work is testing ideas against reality*.

In the next chapter, we're going to look at the concept of Meeting Reality in a bit more depth.

Meeting Reality

In this chapter, we will look at how exposing your Internal Model to reality is in itself a good risk management technique.

3.1 Revisiting the Model

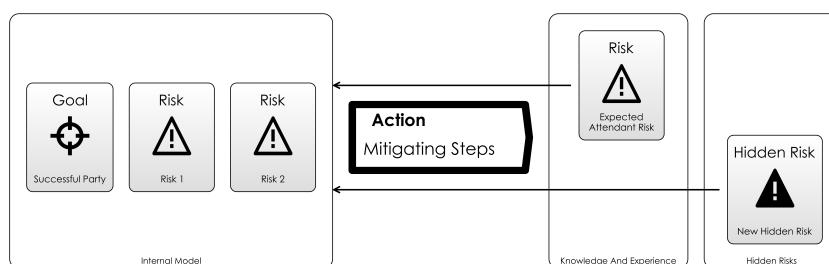

In A Simple Scenario, hoping to **change Reality** with some positive outcome.

And, in Development Process we looked at how we can meet with reality in *different forms*: Analysis, Testing, Integration and so on, and saw how the model could work in each stage of a project.

It should be no surprise to see that there is a *recursive* nature about this:

1. The **actions we take** each day have consequences: they **expose new Hidden Risks
2. The actions we take towards achieving a Goal In Mind.

So, let's see how this kind of recursion looks on our model. Note that here, I am showing *just one possible action*, in reality, you'll have choices.

Hopefully, if you've read along so far, this model shouldn't be too hard to understand. But, how is it helpful?

3.2 “Navigating the Risk Landscape”

So, we often have multiple ways of achieving a Goal In Mind.

What's the best way?

I would argue that the best way is the one which accrues the *least risk* to get it done: each action you take in trying to achieve the overall Goal In Mind, and it's the experience you bring to bear on these that will help you navigate through them smoothly.

Ideally, when you take an action, you are trading off a big risk for a smaller one. Take Unit Testing for example. Clearly, writing Unit Tests adds to the amount of development work, so on its own, it adds Schedule Risk from UAT and adding a smaller risk to **Development**.

You can think of taking actions as moving your project on a “Risk Landscape”: ideally, when you take an action, you move to some place with worse risk to somewhere more favourable.

Figure 3.1: Navigating The Risk Landscape

Sometimes, you can end up somewhere *worse*: the actions you take to solve a higher-level Attendant Risk when you embarked on the action, otherwise you'd not have chosen it.

An Example: Automation

For example, *automating processes* is very tempting: it *should* save time, and reduce the amount of boring, repetitive work on a project. But sometimes, it turns into an industry in itself, and consumes more effort than it's worth.

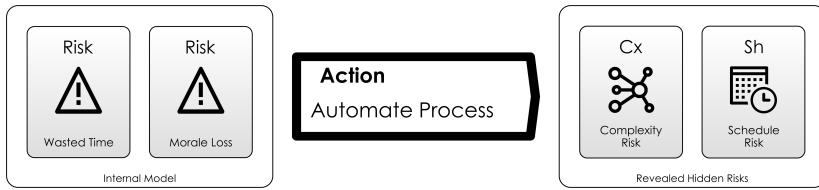

Figure 3.2: Hidden Risks of Automation

Another Quick Example: MongoDB

On a recent project in a bank, we had a requirement to store a modest amount of data and we needed to be able to retrieve it fast. The developer chose to use MongoDB¹ for this. At the time, others pointed out that other teams in the bank had had lots of difficulty deploying MongoDB internally, due to licensing issues and other factors internal to the bank.

Other options were available, but the developer chose MongoDB because of their *existing familiarity* with it: therefore, they felt that the Hidden Risks of MongoDB were *lower* than the other options, and disregarded the others' opinions.

The data storage Attendant Risk of licensing bureaucracy eventually proved too great, and MongoDB had to be abandoned after much investment of time.

This is not a criticism of MongoDB: it's simply a demonstration that sometimes, the cure is worse than the disease. Successful projects are *always* trying to *reduce* Attendant Risks.

3.3 The Cost Of Meeting Reality

Meeting reality is *costly*, for example. Going to production can look like this:

- Releasing software
- Training users
- Getting users to use your system
- Gathering feedback

All of these steps take a lot of effort and time. But you don't have to meet the whole of reality in one go - sometimes that is expensive. But we can meet it in "limited ways".

¹<https://www.mongodb.com>

In all, to de-risk, you should try and meet reality:

- **Sooner**, so you have time to mitigate the hidden risks it uncovers
- **More Frequently**: so the hidden risks don't hit you all at once
- **In Smaller Chunks**: so you're not overburdened by hidden risks all in one go.
- **With Feedback**: if you don't collect feedback from the experience of meeting reality, hidden risks *stay hidden*.

In Development Process earlier. By performing the UAT, we meet reality sooner. The *cost* of this is that we also expend precious time on that process which adds risk to the schedule.

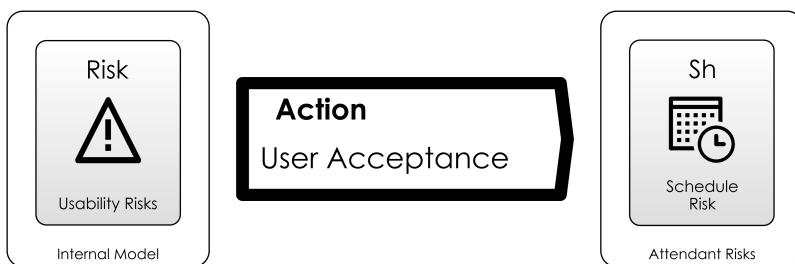

Figure 3.3: Testing flushes out hidden risk, but increases Schedule Risk

YAGNI

As a flavour of what's to come, let's look at YAGNI², an acronym for You Aren't Gonna Need It. Martin Fowler says:

Yagni originally is an acronym that stands for "You Aren't Gonna Need It". It is a mantra from ExtremeProgramming that's often used generally in agile software teams. It's a statement that some capability we presume our software needs in the future should not be built now because "you aren't gonna need it".

This principle was first discussed and fleshed out on Ward's Wiki³

²<https://www.martinfowler.com/bliki/Yagni.html>

³<http://wiki.c2.com/?YouArentGonnaNeedIt>

The idea makes sense: if you take on extra work that you don't need, *of course* you'll be accreting Attendant Risks.

But, there is always the opposite opinion: You *Are Gonna Need It*⁴. As a simple example, we often add log statements in our code as we write it, though following YAGNI strictly says we shouldn't.

Which is right?

Now, we can say: do the work *if it mitigates your Attendant Risks*.

- Logging statements are *good*, because otherwise, you're increasing the risk that in production, no one will be able to understand *how the software went wrong*.
- However, adding them takes time, which might introduce Schedule Risk.

So, it's a trade-off: continue adding logging statements so long as you feel that overall, you're reducing risk.

Do The Simplest Thing That Could Possibly Work

Another mantra from Kent Beck (originator of the Extreme Programming methodology, is "Do The Simplest Thing That Could Possibly Work", which is closely related to YAGNI and is about looking for solutions which are simple. Our risk-centric view of this strategy would be:

- Every action you take on a project has its own Attendant Risks.
- The bigger or more complex the action, the more Attendant Risk it'll have.
- The reason you're taking action *at all* is because you're trying to reduce risk elsewhere on the project
- Therefore, the biggest payoff is whatever action *works* to remove that risk, whilst simultaneously picking up the least amount of new Attendant Risk.

So, "Do The Simplest Thing That Could Possibly Work" is really a helpful guideline for Navigating the Risk Landscape.

⁴<http://wiki.c2.com/?YouAreGonnaNeedIt>

3.4 Summary

So, here we've looked at Meeting Reality, which basically boils down to taking actions to manage risk and seeing how it turns out:

- Each Action you take is a step on the Risk Landscape
- Each Action exposes new Hidden Risks.
- Ideally, each action should reduce the overall Attendant Risk

Could it be that *everything* you do on a software project is risk management? This is an idea explored in the next chapter.

All Risk Management

In this chapter, I am going to introduce the idea that everything you do on a software project is Risk Management.

In the last chapter, we observed that all the activities in a simple methodology had a part to play in exposing different risks. They worked to manage risk prior to them creating bigger problems in production.

Here, we'll look at one of the tools in the Project Manager's toolbox, the RAID Log¹, and observe how risk-centric it is.

4.1 RAID Log

Many project managers will be familiar with the RAID Log. It's simply four columns on a spreadsheet:

- Risks
- Actions
- Issues
- Decisions

Let's try and put the following Attendant Risk into the RAID Log:

Debbie needs to visit the client to get them to choose the logo to use on the product, otherwise we can't size the screen areas exactly.

¹<http://pmtips.net/blog-new/raid-logs-introduction>

- So, is this an **action**? Certainly. There's definitely something for Debbie to do here.
- Is it an **issue**? Yes, because it's holding up the screen-areas sizing thing.
- Is it a **decision**? Well, clearly, it's a decision for someone.
- Is it a **risk**? Probably: Debbie might go to the client and they *still* don't make a decision. What then?

4.2 Let's Go Again

This is a completely made-up example, deliberately chosen to be hard to categorize. Normally, items are more one thing than another. But often, you'll have to make a choice between two categories, if not all four.

This hints at the fact that at some level it's All Risk:

Every Action Attempts to Mitigate Risk

The reason you are *taking* an action is to mitigate a risk. For example:

- If you're coding up new features in the software, this is mitigating Feature Risk.
- If you're getting a business sign-off for something, this is mitigating a Too Many Cooks-style *stakeholder risk*.
- If you're reading the specification, that's mitigating the type of "Developer Misimplementation Risk" we saw in the last chapter.

Every Action Carries Risk.

- How do you know if the action will get completed?
- Will it overrun, or be on time?
- Will it lead to yet more actions?

Consider *coding a feature* (as we did in the earlier Development Process).

And, as we saw in the Introduction, even something *mundane* like the Dinner Party had risks.

An Issue is Just A Type of Risk

- Because issues need to be solved...
- And solving an issue is an action...
- Which, as we just saw also carry risk.

One retort to this might be to say: an issue is a problem I have now, whereas a risk is a problem that *might* occur. I am going to try and *break* that mindset in the coming pages, but I'll just start with this:

- Do you know *exactly* how much damage this issue will do?
- Can you be sure that the issue might not somehow go away?

Issues then, just seem more “definite” and “now” than *risks*, right? This classification is arbitrary: they’re all just part of the same spectrum, so stop agonising over which column to put them in.

Every Decision is a Risk.

- By the very nature of having to make a decision, there’s the risk you’ll decide wrongly.
- And, there’s the time it takes to make the decision.
- And what’s the risk if the decision doesn’t get made?

4.3 Goals Are Risks Too

In the previous chapters, we’ve introduced something of a “diagram language” of risk. Let’s review it:

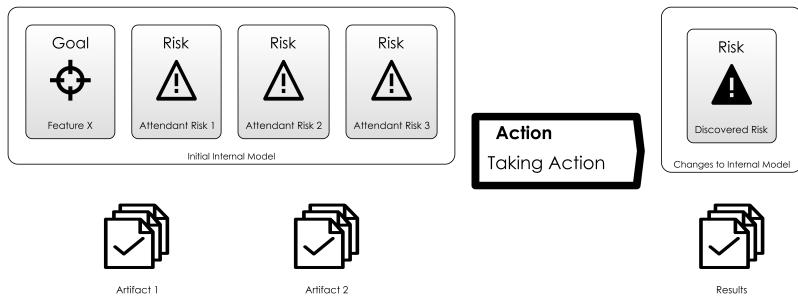

Figure 4.1: Risk-First Diagram Language

So we have:

- Risks.
- Actions.
- Artifacts, which are the results of Meeting Reality.

Goals too. It turns out, that functionally, Goals and Risks are equivalent. For example, The goal of “Implementing Feature X” is equivalent to mitigating “Risk of Feature X not being present”.

Let’s try and back up that assertion with a few more examples:

Goal	Restated As A Risk
Build a Wall	Mitigate the risk of something getting in / out
Land a man on the moon	Mitigate the risk of looking technically inferior during the cold war
Move House	Mitigate the risks/problems of where you currently live

There is a certain “interplay” between the concepts of risks, actions and goals. After all, on the Risk Landscape they correspond to the starting point, a movement, and the destination. From a redundancy perspective, any one of these can be determined by knowing the other two.

Psychologically, humans are very goal-driven: they like to know where they’re going, and are good at organising around a goal. However, by focusing on goals (“solutionizing”) it’s easy to ignore alternatives. By focusing on “Risk-First”, we don’t ignore the reasons we’re doing something.

4.4 Failure

So, when we talk about a project “failing”, what do we mean?

Usually, we mean we’ve failed to achieve a goal, and since *goals are risks*, it is simply the scenario where we are overwhelmed by Attendant Risks and give up.

4.5 What To Do?

It makes it much easier to tackle the RAID log if there’s only one list: all you do is pick either the *most important* risk on the list, or the *most urgent*, or the risk you can make *the biggest impact on*, and deal with it.

In the next chapter, [A Software Project Scenario](Software-Project-Scenario we’ll give an example of this in action.

Software Project Scenario

Where do the risks of the project lie?

How do we decide what *needs to be done today* on a software project?

Let's look again at the simple risk framework from the introduction and try to apply it at the level of the *entire project*.

Figure 5.1: Taking action changes reality, but it changes your perception of the attendant risks too

5.1 Today's Action

How should we decide how to spend our time today?

What actions should we take? (In Scrum.

Let's say that we are working in a Startup, on a project building an online service. As we discussed previously, we could call this a Goal, in order to keep the startup alive.

5.2 Attendant Risks

What are the Attendant Risks that come with that goal? Here are some to get us started:

1. The users can't access the system
2. The data gets lost, stolen.
3. The data is wrong or corrupted
4. There are bugs that prevent the functionality working
5. The functionality isn't there that the user needs (Feature Risk).
6. Our Internal Model of the market is poor, and we could be building the wrong thing.

I'm sure you can think of some more.

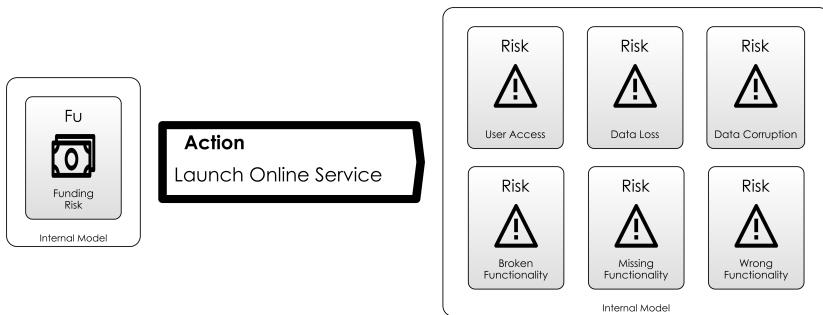

Figure 5.2: Our Goal, With Attendant Risks

5.3 Evaluating The Risks

Next, we can look at each of these risks and consider the threat they represent. The same Attendant Risks will be evaluated differently depending on the *nature of the project* and the mitigations you already have in place. For example:

- If they **can't access it**, does that mean that they're stuck unable to get on the train? Or they can't listen to music?
- If the **data is lost**, does this mean that no one can get on the plane? Or that the patients have to have their CAT scans done again? Or that people's private information is scattered around the Internet?
- If the **data is wrong**, does that mean that the wrong people get sent their parcels? Do they receive the wrong orders? Do they end up going to the wrong courses?
- If the **security is compromised** and all the data exposed, does that mean confidential details are shared on the internet, or that they just need to create a new password?

- If there is **missing functionality**, will they not buy the system? Will they use a competitor's product? Will they waste time doing things a harder or less optimal way?
- If our **Internal Model is wrong**, then is there a chance we are building something for a non-existent market? Or annoying our customers? Or leaving an opportunity for competitors?

A Single Attendant Risk: Getting Hacked

Let's consider a single risk: that the website gets hacked, and sensitive data is stolen. How we evaluate this risk is going to depend on a number of factors:

- How many users we have
- The importance of the data
- How much revenue will be lost
- Risk of litigation
- etc.

Ashley Maddison

In 2016, Ashley Maddison, a website specialising in aiding extra-marital affairs, suffered a data breach¹, revealing the personal details of all of their clients on the internet. The sensitive nature of their business contrasts sharply with the reported sloppiness of their security arrangements.

Can our risk model explain what happened here?

- It's possible that for the developers in question, security concerns were a Hidden Risk: they were not aware of the dangers of being hacked.
- It's possible that *at the time of setting up the security arrangements*, stronger security was considered, but the evaluation of the risk was low: Perhaps, the risk of not shipping quickly was deemed greater. And so they ignored this concern.
- It's also possible that *for Ashley Maddison* the perceived impact of any data-breach was considered low. The impact is on the *customers*, rather than the *company*.
- But, as the number of users of the sites increased, the risk increased too, but there was (apparently) no re-evaluation of the risk otherwise they would have addressed it. This was a costly *failure to update the Internal Model*.

¹https://en.wikipedia.org/wiki/Ashley_Madison_data_breach

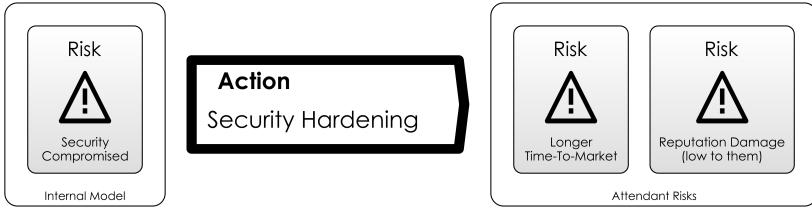

Figure 5.3: Attendant Risks of Improved Security

This story highlights a couple of important lessons. First, when exposing a service on the Internet, it's now a good idea to *look for trouble*: you should go out and try and improve your Internal Model². Thankfully, this is what sites like OWASP³ are for: they *tell you about the Attendant Risks*⁴ and further, try to provide some evaluation of them to guide your actions. Second, you shouldn't expect an organisation with a morally-questionable business model to have your best interests at heart.

5.4 Actions Are Dependent On Risk Evaluation

So, *evaluating risks against one another other* allows us to determine what actions we should pursue on any given day, by answering the question:

Which actions give us the biggest benefit in terms of mitigating Attendant Risk?

For example, it's worth considering that if we're just starting this project, risks 1-4 in our diagram above are *negligible*. It makes complete sense from a risk-evaluation perspective that we're only going to spend time building functionality or improving our understanding of the market.

5.5 Tacit and Explicit Modelling

As we saw in the example of the Dinner Party.

In the next chapter, we're going to take a quick aside into looking at some Risk Theory around this.

Risk Theory

Here, I am going to recap on some pre-existing knowledge about risk, generally, in order to set the scene for the next chapter which heads back to looking at risk on software projects.

6.1 Risk Registers

In the previous chapter Software Project Scenario of the project, in order to decide what to do next.

A Risk Register¹ can help with this. From Wikipedia:

A typical risk register contains:

- A risk category to group similar risks
- The risk breakdown structure identification number
- A brief description or name of the risk to make the risk easy to discuss
- The impact (or consequence) if event actually occurs rated on an integer scale
- The probability or likelihood of its occurrence rated on an integer scale
- The Risk Score (or Risk Rating) is the multiplication of Probability and Impact and is often used to rank the risks.
- Common mitigation steps (e.g. within IT projects) are Identify, Analyze, Plan Response, Monitor and Control.

This is Wikipedia's example:

¹https://en.wikipedia.org/wiki/Risk_register

Category	Name	RBS ID	Probability	Impact	Mitigation	Contingency	Risk Score after Mitigation	Action By	Action When
Guests	The guests find the party boring	1.1.	low	medium	Invite crazy friends, provide sufficient liquor	Bring out the karaoke	2		within 2hrs
Guests	Drunken brawl	1.2.	medium	low	Don't invite crazy friends, don't provide too much liquor	Call 911	x		Now
Nature	Rain	2.1.	low	high	Have the party indoors	Move the party indoors	0		10mins
Nature	Fire	2.2.	highest	highest	Start the party with instructions on what to do in the event of fire	Implement the appropriate response plan	1	Everyone	As per plan

Figure 6.1: Wikipedia Risk Register

Some points about this description:

This is a Bells-and-Whistles Description

Remember back to the Dinner Party example at the start: the Risk Register happened *entirely in your head*. There is a continuum all the way from “in your head” to Wikipedia’s Risk Register description. Most of the time, it’s going to be in your head, or in discussion with the team, rather than written down.

Most of the value of the **Risk-First** approach is *in conversation*. Later, we’ll have an example to show how this can work out.

Probability And Impact

Sometimes, it’s better to skip these, and just figure out a Risk Score. This is because if you think about “impact”, it implies a definite, discrete event occurring, or not occurring, and asks you then to consider the probability of that occurring.

Risk-First takes a view that risks are a continuous quantity, more like *money* or *water*: by taking an action before delivering a project you might add a degree of Schedule Risk later on by a greater amount.

6.2 Graphical Analysis

The Wikipedia page also includes this wonderful diagram showing you risks of a poorly run barbecue party:

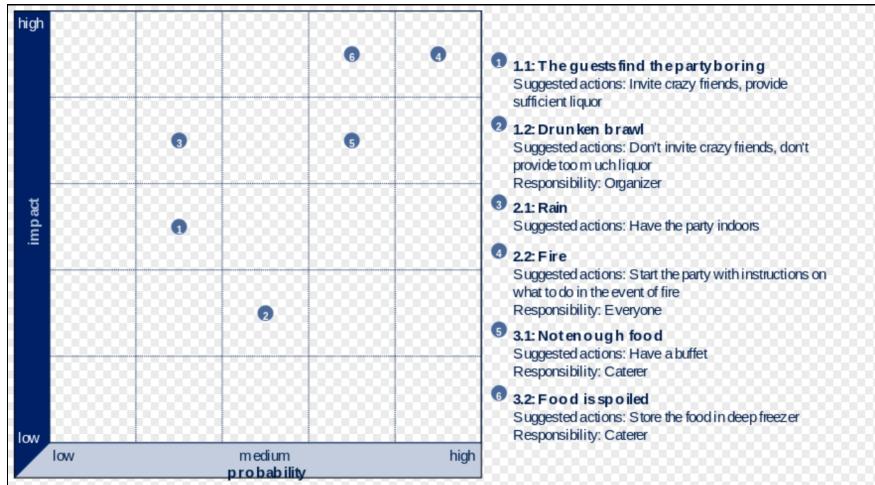

Figure 6.2: Wikipedia Risk Register

This type of graphic is *helpful* in deciding what to do next, although personally I prefer to graph the overall **Risk Score** against the **Cost of Mitigation**: easily mitigated, but expensive risks can therefore be dealt with first (hopefully).

6.3 Unknown Unknowns

In Wikipedia's example, this fictitious BBQ has high fire risk, so one should begin mitigating there.

But, does this feel right? One of the criticisms of the Risk Register. That is, mistakenly believing that what's on the Risk Register *is all there is*.

In the preceding discussions, I have been careful to point out the existence of Hidden Risks for that very reason. Or, to put another way:

What we don't know is what usually gets us killed - Petyr Baelish,
Game of Thrones

Donald Rumsfeld's famous Known Knowns² is also a helpful conceptualization.

²https://en.wikipedia.org/wiki/There_are_known_knowns

6.4 Risk And Uncertainty

Arguably, this site uses the term ‘Risk’ wrongly: most literature suggests risk can be measured³ whereas uncertainty represents things that cannot.

I am using **risk** everywhere because later we will talk about specific risks (e.g. Boundary Risk⁴ or Complexity Risk⁵), and it doesn’t feel grammatically correct to talk about those as **uncertainties**, especially given the pre-existing usage in Banking of terms like Operational Risk⁶ or Reputational risk⁷ which are also not really a-priori measurable.

6.5 The Opposite Of Risk Management

Let’s look at the classic description of Risk Management:

Risk Management is the process of thinking out corrective actions before a problem occurs, while it’s still an abstraction. The opposite of risk management is crisis management, trying to figure out what to do about the problem after it happens. - Waltzing With Bears, Tom De Marco & Tim Lister⁸

This is not how **Risk-First** sees it:

First, we have the notion that Risks are discrete events, again. Some risks *are* (like gambling on a horse race), but most *aren’t*. In the Dinner Party, for example, bad preparation is going to mean a *worse* time for everyone, but how good a time you’re having is a spectrum, it doesn’t divide neatly into just “good” or “bad”.

Second, the opposite of “Risk Management” (or trying to minimize the “Downside”) is either “Upside Risk Management”, (trying to maximise the good things happening), or it’s trying to make as many bad things happen as possible. Humans tend to be optimists (especially when there are lots of Hidden Risks, hence our focus on Downside Risk. Sometimes though, it’s good to stand back and look at a scenario and think: am I capturing all the Upside Risk here?

³<https://keydifferences.com/difference-between-risk-and-uncertainty.html>

⁴Boundary-Risk

⁵Complexity-Risk

⁶https://en.wikipedia.org/wiki/Operational_risk

⁷<https://www.investopedia.com/terms/r/reputational-risk.asp>

⁸<http://amzn.eu/d/i0IDFA2>

Finally, Crisis Management is *still just Risk Management*: the crisis (Earthquake, whatever) has *happened*. You can't manage it because it's in the past. All you can do is Risk Manage the future (minimize further casualties and human suffering, for example).

Yes, it's fine to say "we're in crisis", but to assume there is a different strategy for dealing with it is a mistake: this is the Fallacy of Sunk Costs⁹.

6.6 Invariances #1: Panic Invariance

You would expect then, that any methods for managing software delivery should be *invariant* to the level of crisis in the project. If, for example, a project proceeds using Scrum for eight months, and then the deadline looms and everyone agrees to throw Scrum out of the window and start hacking, then *this implies there is a problem with Scrum*, and that it is not *Panic Invariant*. In fact, many tools like Scrum don't consider this:

- If there is a production outage during the working week, we don't wait for the next Sprint to fix it.
- Although a 40-hour work-week *is a great idea*, this goes out of the window if the databases all crash on a Saturday morning.

In these cases, we (hopefully calmly) *evaluate the risks and take action*.

I call this **Panic Invariance**: the methodology shouldn't need to change given the amount of pressure or importance on the table.

6.7 Invariances #2: Scale Invariance

Another test of a methodology is that it shouldn't fall down when applied at different *scales*. Because, if it does, this implies that there is something wrong with the methodology. The same is true of physical laws: if they don't apply under all circumstances, then that implies something is wrong. For example, Newton's Laws of Motion fail to calculate the orbital period of Mercury, and this was an early win for Einstein's Relativity.

Some methodologies are designed for certain scales: Extreme Programming is designed for small, co-located teams. And, that's useful. But the fact it doesn't scale tells us something about it: chiefly, that it considers certain *kinds* of risk, while ignoring others. At small scales, that works ok, but at larger scales, the bigger risks increase too fast for it to work.

⁹https://en.wikipedia.org/wiki/Sunk_costs

So ideally, a methodology should be applicable at *any* scale: - A single class or function - A collection of functions, or a library - A project team - A department - An entire organisation

If the methodology *fails at a particular scale*, this tells you something about the risks that the methodology isn't addressing. It's fine to have methodologies that work at different scales, and on different problems. One of the things that I am exploring with Risk First is trying to place methodologies and practices within a framework to say *when* they are applicable.

6.8 Value vs Speed

Value

"Upside Risk" isn't a commonly used term: industry tends to prefer "value", as in "Is this a value-add project?". There is plenty of theory surrounding **Value**, such as Porter's Value Chain. This is all fine so long as we remember:

- **The pay-off is risky:** Since the **Value** is created in the future, we can't be certain about it happening - we should never consider it a done-deal. **Future Value** is always at risk. In finance, for example, we account for this in our future cash-flows by discounting them according to the risk of default.
- **The pay-off amount is risky:** Additionally, whereas in a financial transaction (like a loan, say), we might know the size of a future payment, in IT projects we can rarely be sure that they will deliver a certain return. On some fixed-contract projects this sometimes is not true: there may be a date when the payment-for-delivery gets made, but mostly we'll be expecting an uncertain pay-off.

Risk-First is a particular *view* on reality. It's not the only one. However, I am going to try and make the case that it's an underutilized one that has much to offer us.

Speed

For example, in Rapid Development¹⁰ by Steve McConnell we have the following diagram:

And, this is *fine*, McConnell is structuring the process from the perspective of *delivering as quickly as possible*. However, here, I want to turn this on its

¹⁰<http://a.co/d/ddWGTB>

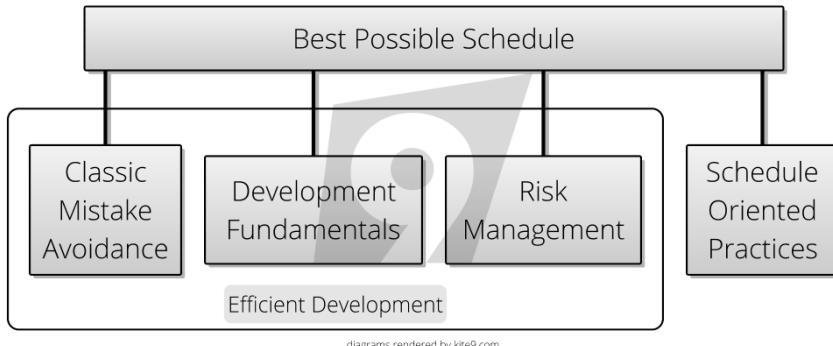

Figure 6.3: Pillars, From Rapid Development By Steve McConnell

head. Exploring Software Development from a risk-first perspective is an under-explored technique, and I believe it offers some useful insights. So the aim here is to present the case for viewing software development like this:

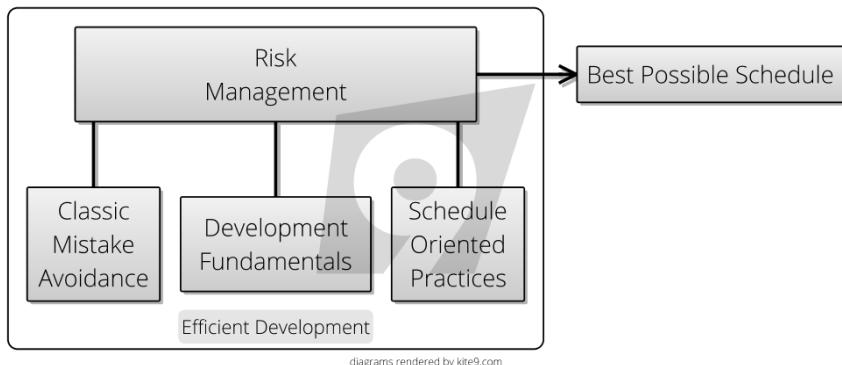

Figure 6.4: Pillars, re-arranged

As we will see, *Speed* (or Schedule Risk, and irreparably damages trust in the product.

Eisenhower's Box

If we can view software delivery from the point of view of *value*, then why can't we apply the same tools to Risk too? In order to do this, let's review "Eisenhower's Box" model. This considers two variables:

- How valuable the work is (Importance)
- How soon it is needed (Urgency)

		Urgent	Not Urgent
Important	Crying baby Kitchen fire Some calls	Exercise Vocation Planning	
	1	2	
Not Important	Interruptions Distractions Other calls	Trivia Busy work Time wasters	
3	4		

Figure 6.5: A basic “Eisenhower box” to help evaluate urgency and importance. Items may be placed at more precise points within each quadrant. - Time Management, Wikipedia¹¹

Here, we’re considering a synthesis of both *time* and *value*. But Net Present Value¹² allows us to discount value in the future, which offers us a way to reconcile these two variables. In the diagram, you can see two future payments, one of č100 due in one year, one of č150 due in 10 years. By discounting at a given rate (here at 6% per year) we can compare their worth *now*.

6.9 Net Present Risk

Can we do the same thing with risk? Let’s introduce the concept of Net Present Risk, or NPR:

Net Present Risk is the *Importance* of a Future risk, discounted to a common level of *Urgency*.

Let’s look at a quick example to see how this could work out. Let’s say you had the following 3 risks:

- Risk A, which will cost you č50 in 5 year’s time.

¹²https://en.wikipedia.org/wiki/Net_present_value

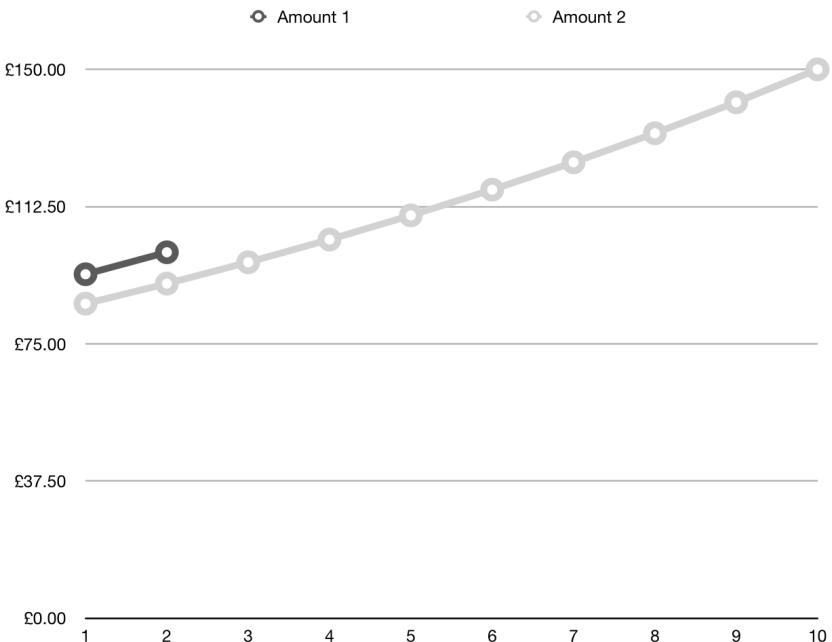

Figure 6.6: Net Present Value Discounting

- Risk **B**, which will cost you £70 in 8 year's time.
- Risk **C**, which will cost you £120 in 18 year's time.

Which has the biggest NPR? Well, it depends on the discount rate that you apply. Let's assume we are discounting at 6% per year. A graph of the discounted risks looks like this:

On this basis, the biggest risk is **B**, at about £45. If we *reduce* the discount factor to 3%, we get a different result:

Now, risk **C** is bigger.

Because this is *Net Present Risk*, we can also use it to make decisions about whether or not to mitigate risks. Let's consider the cost of mitigating each risk *now*:

- Risk **A** costs £20 to mitigate
- Risk **B** costs £50 to mitigate
- Risk **C** costs £100 to mitigate

Which is the best deal?

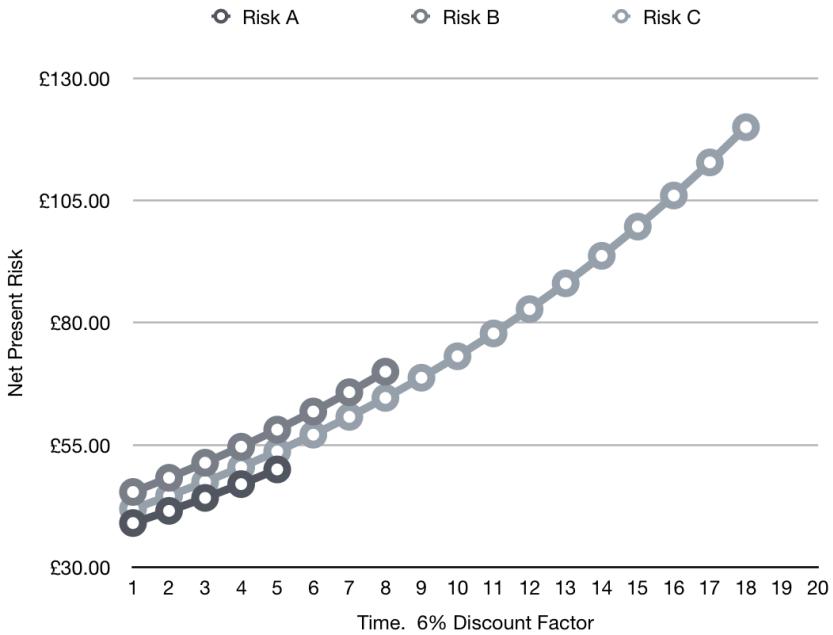

Figure 6.7: Net Present Risk, 6% Discount Rate

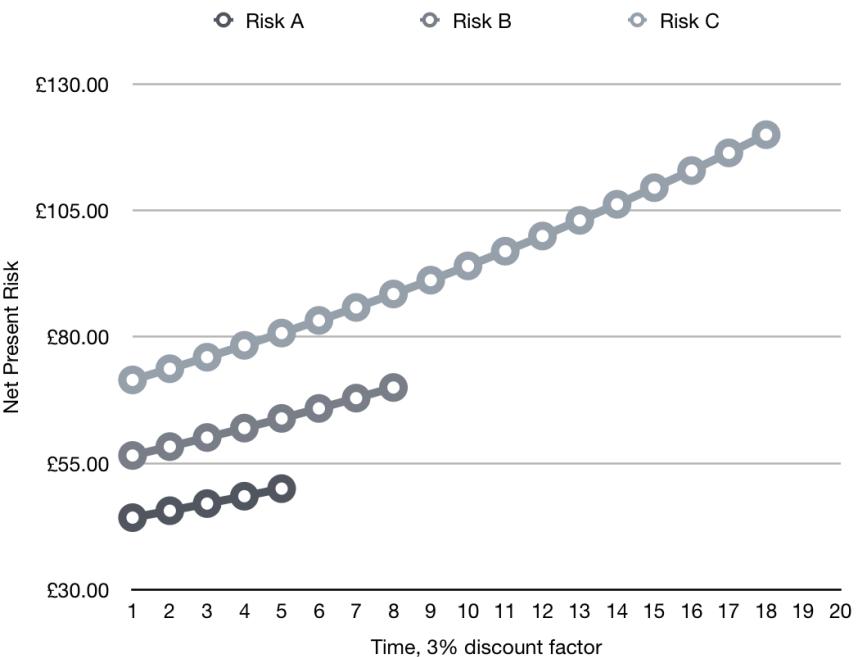

Figure 6.8: Net Present Risk, 3% Discount Rate

Well, under the 6% regime, only Risk **A** is worth mitigating, because you spend £20 today to get rid of £40 of risk (today). The NPR is positive at around £20, whereas for **B** and **C** mitigations it's under water.

But, under a 3% regime, risk **A** and **B** are *both* worth mitigating.

Discounting the Future To Zero

I have worked in teams sometimes where the blinkers go down, and the only thing that matters is *now*. They may apply a rate of 60% per-day, which means that anything with a horizon over a week is irrelevant. Regimes of such hyperinflation¹³ are a sure sign that something has *really broken down* within a project. Consider in this case a Discount Factor of 60% per day, and the following risks:

- Risk A: £80 cost, happening *tomorrow*
- Risk B: £500 cost, happening in *5 days*.

Risk B is almost irrelevant under this regime, as this graph shows:

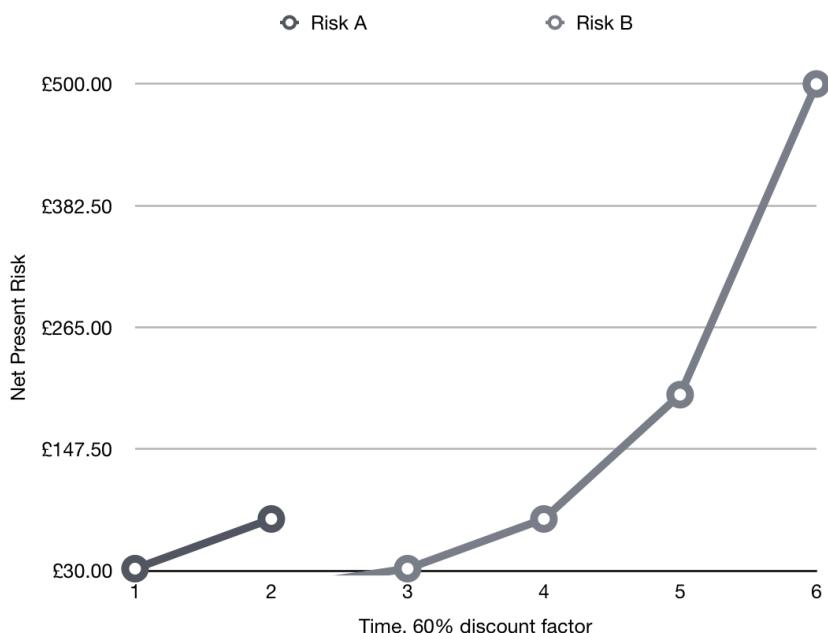

Figure 6.9: Net Present Risk, 60% Discount Rate

¹³<https://en.wikipedia.org/wiki/Hyperinflation>

Why do things like this happen? Often, the people involved are under incredible job-stress: usually they are threatened with the sack on a daily basis, and therefore feel they have to react. Publically-listed companies also often apply short-term focus, because they only care about the *next annual report*, which limits their horizons and ability to consider future risk.

Under these circumstances, we often see *Pooh-Bear Procrastination*:

"Here is Edward Bear coming downstairs now, bump, bump, bump, on the back of his head, behind Christopher Robin. It is, as far as he knows, the only way of coming downstairs, but sometimes he feels that there really is another way... if only he could stop bumping for a moment and think of it!"

—A. A. Milne, *Winnie-the-Pooh*¹⁴

6.10 Is This Scientific?

Enough with the numbers and the theory: **Risk-First** is an attempt to provide a practical framework, rather than a scientifically rigorous analysis. In fact, my view is that you should *give up* on trying to compute risk numerically. You *can't* work out how long a software project will take based purely on an analysis of (say) *function points*. (Whatever you define them to be).

- First, there isn't enough evidence for an approach like this. We *can* look at collected data about IT projects, but techniques and tools change.
- Second, IT projects have too many confounding factors, such as experience of the teams, technologies used etc. That is, the risks faced by IT projects are *too diverse* and *hard to quantify* to allow for meaningful comparison from one to the next.
- Third, as soon as you *publish a date* it changes the expectations of the project (see Student Syndrome).
- Fourth, metrics get first of all misused.

Reality is messy. Dressing it up with numbers doesn't change that and you risk fooling yourself. If this is the case, is there any hope at all in what we're doing? I would argue yes: *forget precision*. You should, with experience be able to hold up two separate risks and answer the question, "is this one bigger than this one?"

With that in mind, let's look at how we can meet reality as fast and often as possible.

¹⁴<http://amzn.eu/d/acJ5a2j>

Cadence

Let's go back to the model again, introduced in Meeting Reality:

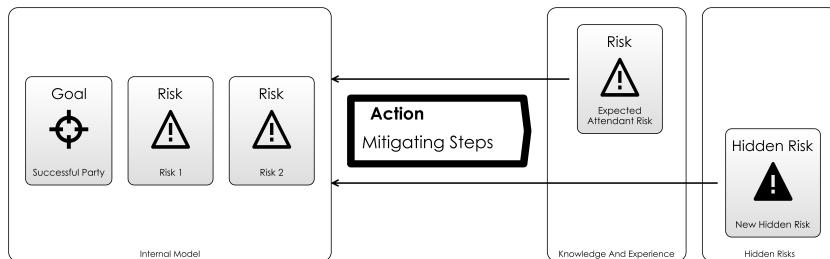

Figure 7.1: Meeting Reality: reality is changed and so is your internal model.

As you can see, it's an idealized **Feedback Loop**.

How *fast* should we go round this loop? Is there a right answer? The longer you leave your goal in mind, the longer it'll be before you find out how it really stacks up against reality.

Testing your goals in mind against reality early and safely is how you'll manage risk effectively, and to do this, you need to set up **Feedback Loops**. e.g.

- **Bug Reports and Feature Requests** tell you how the users are getting on with the software.
- Monitoring Tools and Logs allow you to find out how your software is doing in reality.
- **Dog-Fooding** i.e using the software you write yourself might be faster than talking to users.

- Continuous Delivery is about putting software into production as soon as it's written.
- **Integration Testing** is a faster way of meeting *some* reality than continually deploying code and re-testing it manually.
- **Unit Testing** is a faster feedback loop than Integration Testing.
- **Compilation** warns you about logical inconsistencies in your code.

.. and so on.

Time / Reality Trade-Off

This list is arranged so that at the top, we have the most visceral, most *real* feedback loop, but at the same time, the slowest.

At the bottom, a good IDE can inform you about errors in your Internal Model in real time, by way of highlighting compilation errors . So, this is the fastest loop, but it's the most *limited* reality.

Imagine for a second that you had a special time-travelling machine. With it, you could make a change to your software, and get back a report from the future listing out all the issues people had faced using it over its lifetime, instantly.

That'd be neat, eh? If you did have this, would there be any point at all in a compiler? Probably not, right?

The whole *reason* we have tools like compilers is because they give us a short-cut way to get some limited experience of reality *faster* than would otherwise be possible. Because, cadence is really important: the faster we test our ideas, the more quickly we'll find out if they're correct or not.

Development Cycle Time

One thing that often astounds me is how developers can ignore the fast feedback loops at the bottom of the list, because the ones nearer the top *will do*. In the worst cases, changing two lines of code, running the build script, deploying and then manually testing out a feature. And then repeating.

If you're doing it over and over, this is a terrible waste of time. And, you get none of the benefit of a permanent suite of tests to run again in the future.

The Testing Pyramid¹ hints at this truth:

- **Unit Tests** have a *fast feedback loop*, so have *lots of them*.

¹<http://www.agilenutshell.com/episodes/41-testing-pyramid>

- **Integration Tests** have a slightly *slower feedback loop*, so have *few of them*. Use them when you can't write unit tests (at the application boundaries).
- **Manual Tests** have a *very slow feedback loop*, so have *even fewer of them*. Use them as a last resort.

Production

You could take this chapter to mean that Continuous Delivery is always and everywhere a good idea. I guess that's not a bad take-away, but it's clearly more nuanced than that.

Yes, CD will give you faster feedback loops, but even getting things into production is not the whole story: the feedback loop isn't complete until people have used the code, and reported back to the development team.

The right answer is to use the fastest feedback loop possible, *which actually does give you feed back*.

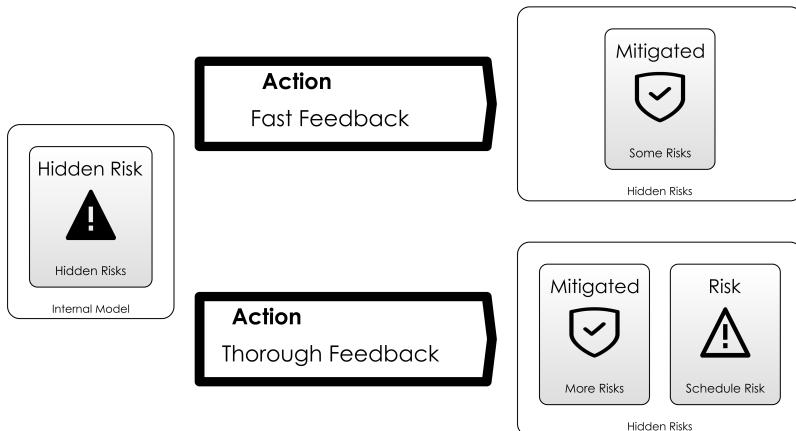

Figure 7.2: Different actions have different feedback loops

7.1 Recap

Let's look at the journey so far:

- In A Simple Scenario of the world couldn't capture everything about reality, and so some things were down to chance.

- In the Development Process we looked at how common software engineering conventions like Unit Testing, User Acceptance Testing and Integration could help us manage the risk of taking an idea to production, by *gradually* introducing it to reality in stages.
- Then, generalizing the lessons of the Development Process article, we examined the idea that Meeting Reality.
- In It's All Risk Management we took a leap of faith: Could *everything* we do just be risk management? And we looked at the RAID log and thought that maybe it could be.
- Next, in A Software Project Scenario we looked at how you could treat the project-as-a-whole as a risk management exercise, and treat the goals from one day to the next as activities to mitigate risk.
- Some Risk Theory was an aside, looking at some terminology and the useful concept of a Risk Register.
- Finally, above, we looked at Cadence more effectively, by showing you more quickly when you're going wrong.

What this has been building towards is supplying us with a vocabulary with which to communicate to our team-mates about which Risks are important to us, which actions we believe are the right ones, and which tools we should use.

Let's have a look at an example of how this might work.

De Risking

As we saw in A Conversation. This is the essence of *De-Risking*.

“To take steps to make (something) less risky or less likely to involve a financial loss.”

—De-Risk, OxfordDictionaries.com¹

Some simple examples of this might be:

- Safety-nets and ropes de-risk climbing. But, the activity of climbing itself is otherwise much unchanged.
- Backups and Source-Control de-risk the development process by reducing the impact of computer failure. Our process is changed *slightly* by this imposition, but we’re not massively inconvenienced.
- tbd.
- tbd.

Let’s look at some common strategies for De-Risking. This is probably not an exhaustive set, but it’s a good starting point.

8.1 Mitigate

Mitigating the risk is taking steps towards minimizing either its likelihood or impact (as we discussed in the Risk Theory)

¹<https://en.oxforddictionaries.com/definition/de-risk>

8.2 Avoid

Avoiding a risk, means taking a route on the Risk Landscape associated with this technology.

Of course, you may pick up other, more serious Attendant Risks problem.

8.3 Transfer

Transferring risk means _making it someone else's problem. For example, when I buy home insurance, the impact of my house burning down is reduced. It hasn't gone away completely, but at least the financial element of it is handled by the insurance company.

In part 2, we'll see how **Transfer** of risk is an essential feature of Software as a Service. Inside organisations, **Transfer** of risk can become a political game:

“... ownership results in ‘one throat to choke’ for audit functions [and] from ownership comes responsibility. A lot of the political footwork in an enterprise revolves around trying to not own technologies. Who wants to be responsible for Java usage across a technology function of dozens of thousands of staff, any of whom might be doing crazy stuff? You first, mate.”

—Why Are Enterprises So Slow?, [zwischenzugs.com](https://zwischenzugs.com/2018/10/02/why-are-enterprises-so-slow/)²

8.4 Ignore / Accept

Accepting a risk is to deal with it when it arises. One example is the Key-Man Risk involved in having a superstar programmer on the team. Although there would be fallout if they left, they are usually mitigating more risk than they cause. Another example is using particular software dependencies: I might build a mobile application which requires a Facebook account to log in. This might give rise to the risk that some people can't log in, but might simplify the software to such an extent that it's worthwhile.

Whereas **Accepting** a risk seems to imply an eyes-wide-open examination, **Ignoring** seems to imply that either the risk is so insignificant it doesn't warrant evaluation, or so daunting that it can't be stared down. Either way, **Ignoring** a risk amounts to the same thing as **Accepting** it, since you're not doing anything about it.

²<https://zwischenzugs.com/2018/10/02/why-are-enterprises-so-slow/>

Accepting a risk has to occur *before* we can **Mitigate** it. As we've discussed previously, what we decide to mitigate on a daily basis will depend on the evaluation of where we can best mitigate Attendant Risk.

A Nice Problem To Have

Ignoring or **Accepting** risks is a lot less work than **Mitigating** them, and sometimes it can feel negligent to just add them to the backlog or risk-register. One useful test I have found is whether "This would be a nice problem to have". For example:

Running out of space in the database would be a nice problem to have, because it would mean we have lots of users

Users complaining about lacking function X would be a nice problem to have, because it would mean they were using the system

Applying this kind of logic at the start of a project leads you towards building a Minimum Viable Product³.

Learned Helplessness

Sometimes, risks just go away on their own. Learned Helplessness⁴ on the other hand, is where we *could* do something about the risk, but fail to see that as an option:

"Learned helplessness is behavior typical of animals, and in rare cases humans, that occurs when the subject endures repeatedly painful or otherwise aversive stimuli which it is unable to escape or avoid. After such experience, the organism often fails to learn or accept "escape" or "avoidance" in new situations where such behavior would likely be effective."

—Learned Helplessness, Wikipedia⁵

³https://en.wikipedia.org/wiki/Minimum_viable_product

⁴https://en.wikipedia.org/wiki/Learned_helplessness

⁵https://en.wikipedia.org/wiki/Learned_helplessness

8.5 Contain

Containing risks means setting aside sufficient time or money to deal with them if they occur. This is an excellent approach for Hidden Risk.

Whenever a project-manager builds slack into a project plan, this is **Containment**. In the chapter on Schedule Risk we are going to look in detail at how this works.

8.6 Exploit

Exploiting as a strategy usually means taking advantage of the upside of a risk. For example, ensuring enough stock is available to mitigate the risk of a rush on sales over the Christmas period, or ensuring your website has enough bandwidth to capture all the traffic headed towards it after it's featured on television.

Going back to the example of home insurance, the Insurance company are **exploiting** the risk of my house burning down by selling me insurance. This is a common pattern: wherever there is risk, there is likely to be a way to profit from it.

Later, in the chapter on Process Risk we'll be looking at how **exploiting risk** can happen organically within a company.

8.7 Isn't It Obvious?

At this point, you might be wondering what all the fuss is about. This stuff is all obvious! It's what we do anyway! Perhaps. Risk management *is* what we do anyway:

“We've survived 200,000 years as humans. Don't you think there's a reason why we survived? We're good at risk management.”

—Nassim Nicholas Taleb, author of *The Black Swan*⁶

The problem is that although all this *is* obvious, it appears to have largely escaped codification within the literature, practices and methodologies of software development. Further, while it is obvious, there is a huge hole: Successful De-Risking depends heavily on individual experience and talent.

If there are three take-aways from Risk-First, it is these:

⁶<https://www.zerohedge.com/news/2018-03-13/taleb-best-thing-society-bankruptcy-goldman-sachs>

- Concentrate on Risks, not Goals (goals are risks in disguise, anyway)
- Every action you take is De-Risking *something* (or should be)
- tbd.

Risk-First has stressed the existence of Hidden Risk lives.

A Conversation

After so much theory, it seems like it's time to look at how we can apply these principles in the real world.

The following is based the summary of an issue from just a few weeks ago. It's heavily edited and anonymized, and I've tried to add the **Risk-First** vocabulary along the way, but otherwise, it's real.

Some background: **Synergy** is an online service with an app-store, and **Eve** and **Bob** are developers working for **Large Corporation LTD**, which wants to have an application accepted into Synergy's app-store.

Synergy's release means that the app-store refresh will happen in a few weeks, so this is something of a hard deadline: if we miss it, the next release will be four months away.

9.1 A Risk Conversation

Eve: We've got a problem with the Synergy security review.

Bob: Tell me.

Eve: Well, you know Synergy did their review and asked us to upgrade our Web Server to only allow TLS version 1.1 and greater?

Bob: Yes, I remember: We discussed it as a team and thought the simplest thing would be to change the security settings on the Web Server, but we all felt it was pretty risky. We decided that in order to flush out Hidden Risk, we'd upgrade our entire production site to use it *now*, rather than wait for the app launch.

Eve: Right, and it *did* flush out Hidden Risk: some people using Windows 7, downloading Excel spreadsheets on the site, couldn't download them: for

some reason, that combination didn't support anything greater than TLS version 1.0. So, we had to back it out.

Bob: Ok, well I guess it's good we found out *now*. It would have been a disaster to discover this after the go-live.

Eve: Yes. So, what's our next-best action to mitigate this?

Bob: Well, we could go back to Synergy and ask them for a reprieve, but I think it'd be better to mitigate this risk now if we can... they'll definitely want it changed at some point.

Eve: How about we run two web-servers? One for the existing content, and one for our new Synergy app? We'd have to get a new external IP address, handle DNS setup, change the firewalls, and then deploy a new version of the Web Server software on the production boxes.

Bob: This feels like there'd be a lot of Attendant Risk as we go.

Eve: Well, you're correct on the first one. But, I've done this before not that long ago for a Chinese project, so I know the process - we shouldn't run into any new Hidden Risk.

Bob: Ok, fair enough. But isn't there something simpler we can do? Maybe some settings in the Web Server?

Eve: Well, if we were using Apache, yes, it would be easy to do this. But, we're using Baroque Web Server, and it *might* support it, but the documentation isn't very clear.

Bob: Ok, and upgrading it is a *big* risk, right? We'd have to migrate all of our configuration...

Eve: Yes, let's not go there. But if we changing the settings on Baroque, we have the Attendant Risk with the security changes that we don't know about yet.

Bob: Ok, I can see that buys us something, but time is really short and we have holidays coming up.

Eve: Yes. How about for now, we go with the isolated server, and review next week? If it's working out, then great, we continue with it. Otherwise, if we're not making progress next week, then it'll be because our isolation solution is meeting more risk than we originally thought. We can try the settings change in that case.

Bob: Fair enough, it sounds like we're managing the risk properly, and because we can hand off a lot of this to the Networking Team, we can get on

with mitigating our biggest risk on the project, the authentication problem, in the meantime.

Eve: Right. I'll check in with the Networking Team each day and make sure it doesn't get forgotten.

9.2 Aftermath

Hopefully, this type of conversation will feel familiar. It should. There's nothing ground-breaking at all in what we've covered so far; it's more-or-less just Risk Management theory.

If you can now apply it in conversation, like we did above, then that's one extra tool you have for delivering software.

So with the groundwork out of the way, let's get on to Part 2 and investigate The Risk Landscape.

Part II

Risk

Risk Landscape

Risk is messy. It's not always easy to tease apart the different components of risk and look at them individually. Let's look at a high-profile recent example to see why.

10.1 The Financial Crisis

In the Financial Services¹ industry, whole *departments* exist to calculate things like:

- Market Risk²: the risk that the amount some asset you hold/borrow/have loaned is going to change in value.
- Credit Risk³: the risk that someone who owes you a payment at a specific point in time might not pay it back.
- Liquidity Risk⁴: the risk that you can't find a market to sell/buy something, usually leading to a shortage of ready cash.

... and so on. But, we don't need to know the details exactly to understand this story.

They get expressed in ways like this:

we have a 95% chance that today we'll lose less than č100

¹https://en.wikipedia.org/wiki/Financial_services

²https://en.wikipedia.org/wiki/Market_risk

³https://en.wikipedia.org/wiki/Credit_risk

⁴https://en.wikipedia.org/wiki/Liquidity_risk

In the financial crisis, though, these models of risk didn't turn out to be much use. Although there are lots of conflicting explanations of what happened, one way to look at it is this:

- Liquidity difficulties (i.e. amount of cash you have for day-to-day running of the bank) caused some banks to not be able to cover their interest payments.
- This caused credit defaults (the thing that Credit Risk⁵ measures were meant to guard against) even though the banks *technically* were solvent.
- That meant that, in time, banks got bailed out, share prices crashed and there was lots of Quantitative Easing⁶.
- All of which had massive impacts on the markets in ways that none of the Market Risk models foresaw.

All the Risks⁷ were correlated⁸. That is, they were affected by the *same underlying events, or each other*.

10.2 The Risk Landscape Again

It's like this with software risks, too, sadly.

In Meeting Reality, and how a software project tries to *navigate* across this landscape, testing the way as it goes, and trying to get to a position of *more favourable risk*.

It's tempting to think of our Risk Landscape⁹ as being like a Fitness Landscape¹⁰. That is, you have a "cost function" which is your height above the landscape, and you try and optimise by moving downhill in a Gradient Descent¹¹ fashion.

However, there's a problem with this: As we said in Risk Theory.

I am going to try and show you some of the fauna of the Risk Landscape is also different. But, just as I can tell you that the landscape outside your window will probably will have some roads, trees, fields, forests, buildings, and that the buildings are likely to be joined together by roads, I can tell you some general things about risks too.

⁷Glossary#Risk

⁸<https://www.investopedia.com/terms/c/correlation.asp>

⁹Risk-Landscape

¹⁰https://en.wikipedia.org/wiki/Fitness_landscape

¹¹https://en.wikipedia.org/wiki/Gradient_descent

In fact, we're going to try and categorize the kinds of things we see on this Risk Landscape. But, this isn't going to be perfect:

- One risk can "blend" into another just like sometimes a "field" is also a "car-park" or a building might contain some trees (but isn't a forest).
- There is *correlation* between different risks: one risk may cause another, or two risks may be due to the same underlying cause.
- As we saw in Part 1, mitigating one risk can give rise to another, so risks are often *inversely correlated*.

10.3 Why Should We Categorize The Risks?

This is a "spotters' guide" to risks, not an in-depth encyclopedia.

If we were studying insects, this might be a guide giving you a description and a picture of each insect, telling you where to find it and what it does. That doesn't mean that this is *all* there is to know. Just as a scientist could spend her entire life studying a particular species of bee, each of the risks we'll look at really has a whole sub-discipline of Computer Science attached to it, which we can't possibly hope to cover all of.

As software developers, we can't hope to know the detailed specifics of the whole discipline of Complexity Theory¹², or Concurrency Theory¹³. But, we're still required to operate in a world where these things exist. So, we may as well get used to them, and ensure that we respect their primacy. We are operating in *their* world, so we need to know the rules.

10.4 We're all Naturalists Now

This is a new adventure. There's a long way to go. Just as naturalists are able to head out and find new species of insects and plants, we should expect to do the same. This is by no means a complete picture - it's barely a sketch.

It's a big, crazy, evolving world of software. Help to fill in the details. Report back what you find.

10.5 Our Tour Itinerary

Below is a table outlining the different risks we'll see. There *is* an order to this: the later risks are written assuming a familiarity with the earlier ones.

¹²https://en.wikipedia.org/wiki/Complexity_theory

¹³[https://en.wikipedia.org/wiki/Concurrency_\(computer_science\)](https://en.wikipedia.org/wiki/Concurrency_(computer_science))

Hopefully, you'll stay to the end and see everything, but you're free to choose your own tour if you want to.

Risk	Description
Feature Risk	When you haven't built features the market needs, or they contain bugs, or the market changes underneath you.
Communication Risk	Risks associated with getting messages heard and understood.
Complexity Risk	Your software is so complex it makes it hard to change, understand or run.
Dependency Risk	Risks of depending on other people, products, software, functions, etc. This is a general look at dependencies, before diving into specifics like...
Schedule Risk.	
Software Dependency Risk	When you choose to depend on a software library, service or function.
Process Risk	When you depend on a business process, or human process to give you something you need.
Boundary Risk and it's hard to get back to where you want to be.	
Agency Risk, which might not align with those of the project or team.	
Coordination Risk	Risks due to the fact that systems contain multiple agents, which need to work together.
Map And Territory Risk	
Operational Risk	Software is embedded in a system containing people, buildings, machines and other services. Operational risk considers this wider picture of risk associated with running a software service or business in the real world.

On each page we'll start by looking at the category of the risk *in general*, and then break this down into some specific subtypes. At the end, in Staging

and Classifying we'll have a recap about what we've seen and make some guesses about how things fit together.

So, let's get started with Feature Risk.

Feature Risk

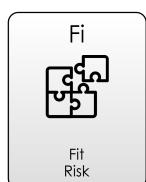

Feature Risk is the category of software risk to do with features that have to be in your software. It is the risk that you face by *not having features that your clients need*.

In a way, Feature Risk is very fundamental: if there were *no* feature risk, the job would be done already, either by you, or by another product, and the product would be perfect!

As a simple example, if your needs are served perfectly by Microsoft Excel, then you don't have any Feature Risk.

Not considering Feature Risk means that you might be building the wrong functionality, for the wrong audience or at the wrong time. And eventually, this will come down to lost money, business, acclaim, or whatever else reason you are doing your project for. So let's unpack this concept into some of its variations.

11.1 Feature Fit Risk

- Risk that the needs of the client don't coincide with services provided by the supplier.

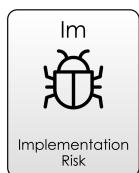

Figure 11.1: Feature Risk

This is the one we've just discussed above: the feature that you (or your clients) want to use in the software *isn't there*. Now, as usual, you could call this an issue, but we're calling it a Risk because it's not clear exactly *how many* people are affected, or how badly.

- This might manifest itself as complete *absence* of something you need, e.g "Where is the word count?"
- It could be that the implementation isn't complete enough, e.g "why can't I add really long numbers in this calculator?"

Features Don't Work Properly

Feature Risk¹ also includes things that don't work as expected: That is to say, bugs². Although the distinction between "a missing feature" and "a broken feature" might be worth making in the development team, we can consider these both the same kind of risk: *the software doesn't do what the user expects*.

- Risk that the functionality you are providing doesn't match the features the client is expecting, due to poor or partial implementation.

Figure 11.2: Implementation Risk

(At this point, it's worth pointing out that sometimes, *the user expects the wrong thing*. This is a different but related risk, which could be down to Training

11.2 Regression Risk

Regression Risk of the whole thing.

Also, while delivering new features can delight your customers, breaking existing ones will annoy them. This is something we'll come back to in Reputation Risk.

- Risk that the functionality you provide changes for the worse, over time.

Figure 11.3: Regression Risk

- Risk that the software you provide is too complex, or doesn't match the expectations of your clients' internal models.

Figure 11.4: Conceptual Integrity Risk

11.3 Conceptual Integrity Risk

Sometimes, users *swear blind* that they need some feature or other, but it runs at odds with the design of the system, and plain *doesn't make sense*. Often, the development team can spot this kind of conceptual failure as soon as it enters the Backlog. Usually, it's in coding that this becomes apparent.

Sometimes, it can go for a lot longer. I once worked on some software that was built as a score-board within a chat application. However, after we'd added much-asked-for commenting and reply features to our score-board, we realised we'd implemented a chat application *within a chat application*, and had wasted our time enormously.

Feature Phones³ are a real-life example: although it *seemed* like the market wanted more and more features added to their phones, Apple's iPhone⁴ was able to steal huge market share by presenting a much more enjoyable, more coherent user experience, despite being more expensive and having fewer features. Feature Phones had been drowning in increasing Conceptual

¹Feature-Risk

²https://en.wikipedia.org/wiki/Software_bug

³https://en.wikipedia.org/wiki/Feature_phone

⁴<https://en.wikipedia.org/wiki/IPhone>

Integrity Risk⁵ without realising it.

Which leads to Greenspun's 10th Rule:

"Any sufficiently complicated C or Fortran program contains an ad-hoc, informally-specified, bug-ridden, slow implementation of half of Common Lisp."

—Greenspun's 10th Rule, Wikipedia⁶

This is a particularly pernicious kind of Feature Risk. Human needs are fractal in nature: the more you examine them, the more differences you can find. The aim of a product is to capture some needs at a *general* level: you can't hope to "please all of the people all of the time".

Conceptual Integrity Risk is the risk that chasing after features leaves the product making no sense, and therefore pleasing no-one.

11.4 Feature Access Risk

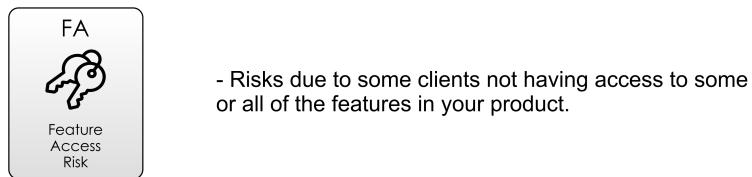

Figure 11.5: Feature Access Risk

Sometimes, features can work for some people and not others: this could be down to Accessibility⁷ issues, language barriers or localization.

You could argue that the choice of *platform* is also going to limit access: writing code for XBox-only leaves PlayStation owners out in the cold. This is largely Feature Access Risk is related here.

In Marketing, minimizing Feature Access Risk.

Market Risk

Feature Access Risk on it:

⁵Feature-Risk#Conceptual-integrity-risk

⁶https://en.wikipedia.org/wiki/Greenspun%27s_tenth_rule

⁷<https://en.wikipedia.org/wiki/Accessibility>

- Risk that the value your clients place on the features you supply will change, over time.

Figure 11.6: Market Risk

“Market risk is the risk of losses in positions arising from movements in market prices.”

—Market Risk, Wikipedia⁸

I face market risk when I own (i.e. have a *position* in) some Apple⁹ stock. Apple’s¹⁰ stock price will decline if a competitor brings out an amazing product, or if fashions change and people don’t want their products any more.

In the same way, *you* have Market Risk on the product or service you are building: the *market* decides what it is prepared to pay for this, and it tends to be outside your control.

11.5 Feature Drift Risk

- Risk that the features required by clients will change and evolve over time.

Figure 11.7: Feature Drift Risk

Feature Drift is the tendency that the features people need *change over time*. For example, at one point in time, supporting IE6 was right up there for

⁸https://en.wikipedia.org/wiki/Market_risk

⁹<http://apple.com>

¹⁰<http://apple.com>

website developers, but it's not really relevant anymore. Although that change took *many* years to materialize, other changes are more rapid.

The point is: Requirements captured *today* might not make it to *tomorrow*, especially in the fast-paced world of IT. This is partly because the market *evolves* and becomes more discerning. This happens in several ways:

- Features present in competitor's versions of the software become *the baseline*, and they're expected to be available in your version.
- Certain ways of interacting become the norm (e.g. query).
- Features decline in usefulness: *Printing* is less important now than it was, for example.

Feature Drift Risk uncovered on the project as it progresses.

Fashion

Fashion plays a big part in IT, as this infographic on website design shows¹¹. True, websites have got easier to use as time has gone by, and users now expect this. Also, bandwidth is greater now, which means we can afford more media and code on the client side. However, *fashion* has a part to play in this.

By being *fashionable*, websites are communicating: *this is a new thing, this is relevant, this is not terrible*: all of which is mitigating a Communication Risk. Users are all-too-aware that the Internet is awash with terrible, abandoned sites that are going to waste their time. How can you communicate that you're not one of them to your users?

11.6 Delight

If this breakdown of Feature Risk, but should be treated in the usual Risk-First way: *pick the biggest risk you can mitigate next*.

Consider Feature Risk from both the down-side and the up-side:

- What are we missing?
- How can we be *even better*?

Hopefully, this has given you some ideas about what Feature Risk and how it affects what we build.

¹¹<https://designers.hubspot.com/blog/the-history-of-web-design-infographic>

11.7 Analysis

At this point, it would be easy to stop and say, look, here are a bunch of Feature Risk as we go on in order to build our understanding of other risks, so it's probably worth spending a bit of time up front to classify what we've found.

The Feature Risks identified here basically exist in a 3-dimensional space:

- **Fit:** How well the features fit for a particular client.
- **Audience:** The range of clients (the *market*) that may be able to use this feature.
- **Evolution:** The way the fit and the audience changes and evolves as time goes by.

Fit

“This preservation, during the battle for life, of varieties which possess any advantage in structure, constitution, or instinct, I have called Natural Selection; and Mr. Herbert Spencer has well expressed the same idea by the Survival of the Fittest”

—Charles Darwin (*Survival of the Fittest*), *Wikipedia*¹².

Darwin's conception of fitness was not one of athletic prowess, but how well an organism worked within the landscape, with the goal of reproducing itself.

Fit Risk all hint at different aspects of this “fitness”. We can conceive of them as the gaps between the following entities:

- Perceived Need: What the user *thinks* they want
- Expectation: What the user *expects*
- Reality: What they actually *get*.

For further reading, you can check out The Service Quality Model¹³, which this model is derived from. This model analyses the types of *quality gaps* in services, and how consumer expectations and perceptions of a service arise. In Staging And Classifying¹⁴, we'll come back and build on this model further.

¹²https://en.wikipedia.org/wiki/Survival_of_the_fittest

¹³<http://en.wikipedia.org/SERVQUAL>

¹⁴[Staging-And-Classifying#Your-Feature-Risk-is-Someone-Else-s-Dependency-Risk](#)

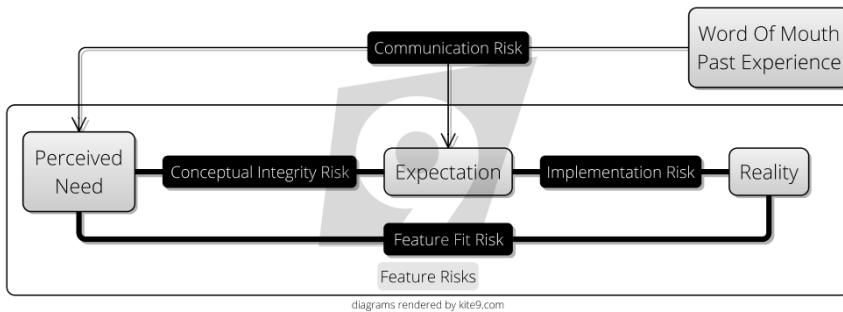

Figure 11.8: Feature Risks Assembled: Fit Risks

Fit and Audience

Two risks, Feature Access Risk rollercoaster, being one moment highly valued and the next irrelevant.

Fit, Audience and Evolution

Two risks further consider how the **Fit** and **Audience** change: Regression Risk. We call this *evolution* in the sense that:

- Our product's features *evolve* with time, and changes made by the development team.
- Our audience changes and evolves as it is exposed to our product and competing products.
- The world as a whole is an evolving system within which our product exists.

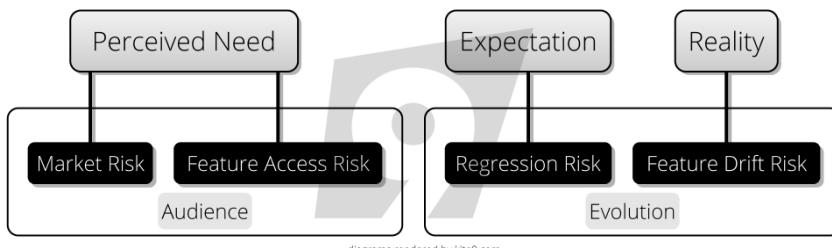

Figure 11.9: Feature Risks Assembled: Audience and Evolution

11.8 Applying Feature Risk

Consider Feature Risk carefully next time you are grooming the backlog:

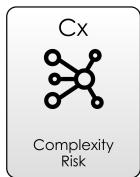

- Can you judge which tasks mitigate the most Feature Risk?
- Are you delivering features that are valuable to a large audience? How well do you understand your audience? How does the size of the audience for a task impact its importance in the backlog?
- Does the audience *know* that the features exist? How do you communicate feature availability to them?
- How does writing a specification mitigate Fit Risk? For what other reasons are you writing specifications?

In the next chapter, we are going to unpack this third point further. Somewhere between “what the customer wants” and “what you give them” is a *dialog*. In using a software product, users are engaging in a *dialog* with its features. If the features don’t exist, hopefully they will engage in a dialog with the development team to get them added.

These dialogs are prone to risk, and this is the subject of the next chapter, Communication-Risk.

Complexity Risk

Complexity Risk. However, in this chapter, we're going to be specifically focusing on *code you write*: the size of your code-base, the number of modules, the interconnectedness of the modules and how well-factored the code is.

- Risks caused by the weight of complexity in the systems we create, and their resistance to change and comprehension.

Figure 12.1: Complexity Risks

You could think of this chapter, then, as **Codebase Risk**: We'll look at three separate measures of codebase complexity and talk about Technical Debt, and look at places in which **Codebase Risk** is at its greatest.

12.1 Kolmogorov Complexity

The standard Computer-Science definition of complexity, is Kolmogorov Complexity¹. This is:

“...is the length of the shortest computer program (in a pre-determined programming language) that produces the object as output.” - Kolmogorov Complexity, Wikipedia

¹https://en.wikipedia.org/wiki/Kolmogorov_complexity

This is a fairly handy definition for us, as it means that to in writing software to solve a problem, there is a lower bound on the size of the software we write. In practice, this is pretty much impossible to quantify. But that doesn't really matter: the techniques for *moving in that direction* are all that we are interested in, and this basically amounts to compression.

Let's say we wanted to write a javascript program to output this string:

We might choose this representation:

```
function out() { (7 )  
    return "abcdabcdabcdabcdabcdabcdabcdabcdabcdabcd" (45)  
} (1 )
```

The numbers in brackets indicate how many symbols each line contains, so in total, this code block contains **53 symbols**, if you count function, out and return as one symbol each.

But, if we write it like this:

```
const ABCD="ABCD"; (11)

function out() { (7)
    return ABCD+ABCD+ABCD+ABCD+ABCD+ABCD+ABCD+
           ABCD+ABCD+ABCD; (6)
} (1)
```

With this version, we now have **41 symbols** (**ABCD** is a single symbol, because we could have called it anything). And with this version:

```
const ABCD="ABCD"; (11)

function out() { (7)
    return ABCD.repeat(10) (7)
}
} (1)
```

... we have 26 symbols.

Abstraction

What's happening here is that we're *exploiting a pattern*: we noticed that ABCD occurs several times, so we defined it a single time and then used it over and over, like a stamp. Separating the *definition* of something from the *use* of something as we've done here is called "abstraction". We're going to come across it over and over again in this part of the book, and not just in terms of computer programs.

By applying techniques such as Abstraction, we can improve in the direction of the Kolmogorov limit. And, by allowing ourselves to say that *symbols* (like `out` and `ABCD`) are worth one complexity point, we've allowed that we can be descriptive in our function name and `const`. Naming things is an important part of abstraction, because to use something, you have to be able to refer to it.

Trade-Off

But we could go further down into Code Golf² territory. This javascript program plays FizzBuzz³ up to 100, but is less readable than you might hope:

```
for(i=0;i<100;)document.write(((++i%3?'Fizz':(i%5?'Buzz'):i)+"<br>"))
```

(62)

So there is at some point a trade-off to be made between Complexity Risk is about *misunderstanding*: The more complex a piece of software is, the more difficulty users will have understanding it, and the more difficulty developers will have changing it.

12.2 Connectivity

A second, useful measure of complexity comes from graph theory, and that is the connectivity of a graph:

"... the minimum number of elements (nodes or edges) that need to be removed to disconnect the remaining nodes from each other"

—Connectivity, Wikipedia⁴

²https://en.wikipedia.org/wiki/Code_golf

³https://en.wikipedia.org/wiki/Fizz_buzz

⁴[https://en.wikipedia.org/wiki/Connectivity_\(graph_theory\)](https://en.wikipedia.org/wiki/Connectivity_(graph_theory))

To see this in action, have a look at the below graph:

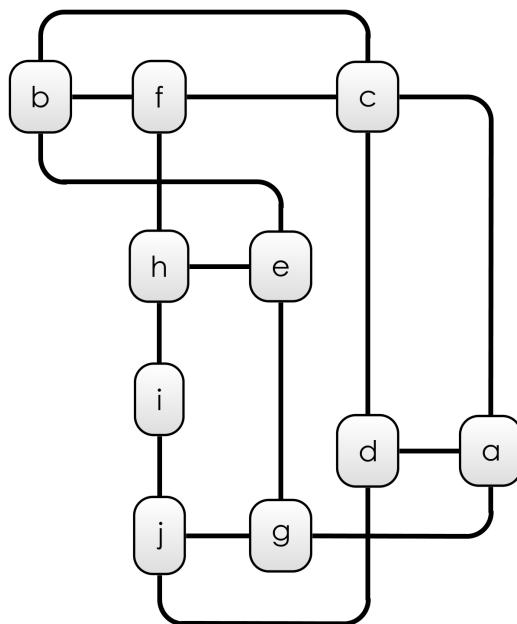

Figure 12.2: Graph 1

It has 10 vertices, labelled **a** to **j**, and it has 15 edges (or links) connecting the vertices together. If any single edge were removed from this diagram, the 10 vertices would still be linked together. Because of this, we can say that the graph is **2-connected**. That is, to disconnect any single vertex, you'd have to remove *at least* two edges.

As a slight aside, let's consider the **Kolmogorov Complexity** of this graph, by inventing a mini-language to describe graphs. It could look something like this:

```
<item> : [<item>,]* <item>      # Indicates that the item
# before the colon
# has a connection to all
# the items after the colon
```

So our graph could be defined like this:

```

a: b,c,d
b: c,f,e
c: f,d
d: j
e: h,j
f: h
g: j
h: i
i: j

```

(39)

Let's remove some of those extra links:

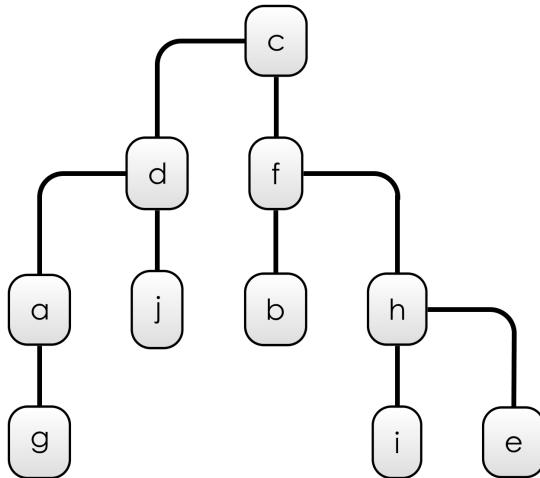

Figure 12.3: Graph 2

In this graph, I've removed 6 of the edges. Now, we're in a situation where if any single edge is removed, the graph becomes *unconnected*. That is, it's broken into distinct chunks. So, it's *1-connected*.

The second graph is clearly simpler than the first. And, we can show this by looking at the **Kolgomorov Complexity** in our little language:

```

a: d,g
b: f

```

```
c: d, f  
d: j  
f: h  
e: h  
h: i
```

(25)

Connectivity is also **Complexity**. Heavily connected programs/graphs are much harder to work with than less-connected ones. Even *laying out* the first graph sensibly is a harder task than the second (the second is a doddle). But the reason programs with greater connectivity are harder to work with is that changing one module potentially impacts many others.

12.3 Hierarchies and Modularization

In the second, simplified graph, I've arranged it as a hierarchy, which I can do now that it's only 1-connected. For 10 vertices, we need 9 edges to connect everything up. It's always:

```
edges = vertices - 1
```

Note that I could pick any hierarchy here: I don't have to start at **c** (although it has the nice property that it has two roughly even sub-trees attached to it).

How does this help us? Imagine if **a - j** were modules of a software system, and the edges of the graph showed communications between the different sub-systems. In the first graph, we're in a worse position: who's in charge? What deals with what? Can I isolate a component and change it safely? What happens if one component disappears? But, in the second graph, it's easier to reason about, because of the reduced number of connections and the new hierarchy of organisation.

On the downside, perhaps our messages have farther to go now: in the original **i** could send a message straight to **j**, but now we have to go all the way via **c**. But this is the basis of Modularization⁵ and Hierarchy⁶.

As a tool to battle complexity, we don't just see this in software, but everywhere in our lives. Society, business, nature and even our bodies:

⁵https://en.wikipedia.org/wiki/Modular_programming

⁶<https://en.wikipedia.org/wiki/Hierarchy>

- **Organelles** - such as Mitochondria⁷.
- **Cells** - such as blood cells, nerve cells, skin cells in the Human Body⁸.
- **Organs** - like hearts livers, brains etc.
- **Organisms** - like you and me.

The great complexity-reducing mechanism of modularization is that *you only have to consider your local environment*. Elements of the program that are “far away” in the hierarchy can be relied on not to affect you. This is somewhat akin to the **Principal Of Locality**:

“Spatial locality refers to the use of data elements within relatively close storage locations.”

—Locality Of Reference, *Wikipedia*⁹

12.4 Cyclomatic Complexity

A variation on this graph connectivity metric is our third measure of complexity, Cyclomatic Complexity¹⁰. This is:

$$\text{Cyclomatic Complexity} = \text{edges} - \text{vertices} + 2P,$$

Where **P** is the number of **Connected Components** (i.e. distinct parts of the graph that aren’t connected to one another by any edges).

So, our first graph had a **Cyclomatic Complexity** of 7. ($15 - 10 + 2$), while our second was 1. ($9 - 10 + 2$).

Cyclomatic complexity is all about the number of different routes through the program. The more branches a program has, the greater it’s cyclomatic complexity. Hence, this is a useful metric in Testing: the more branches you have, the more tests you’ll need to exercise them all.

12.5 More Abstraction

Although we ended up with our second graph having a **Cyclomatic Complexity** of 1 (the minimum), we can go further through abstraction, because this representation isn’t minimal from a **Kolmogorov Complexity** point-of-view. For example, we might observe that there are further similarities in the graph that we can “draw out”:

⁷<https://en.wikipedia.org/wiki/Mitochondrion>

⁸https://en.wikipedia.org/wiki/List_of_distinct_cell_types_in_the_adult_human_body

⁹https://en.wikipedia.org/wiki/Locality_of_reference

¹⁰https://en.wikipedia.org/wiki/Cyclomatic_complexity

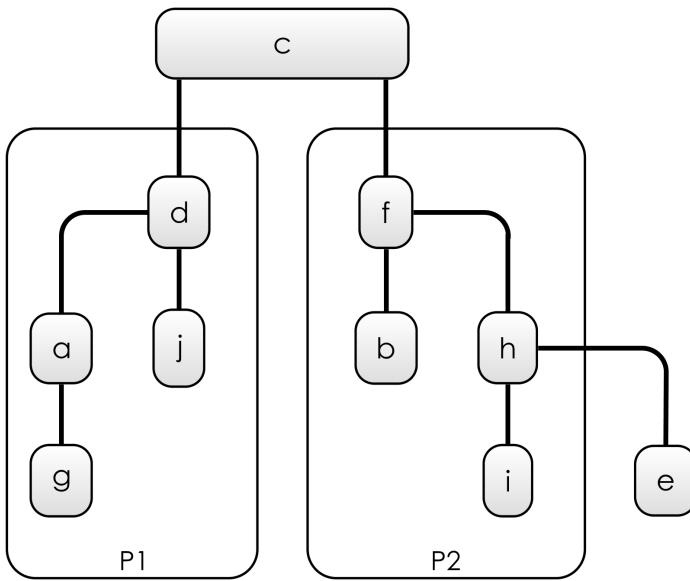

Figure 12.4: Complexity 3

Here, we've spotted that the structure of subgraphs **P1** and **P2** are the same: we can have the same functions there to assemble those. Noticing and exploiting patterns of repetition is one of the fundamental tools we have in the fight against Complexity Risk.

So, we've looked at some measures of software structure complexity, in order that we can say "this is more complex than this". However, we've not really said why complexity entails Risk.

12.6 Complexity As Mass

The first way to look at complexity is as **Mass** or **Inertia**: a software project with more complexity has greater **Inertia** or **Mass** than one with less complexity.

Newton's Second Law states:

“ $F = ma$, (Force = Mass x Acceleration)”

—Netwon’s Laws Of Motion, Wikipedia¹¹

That is, in order to move your project *somewhere new*, and make it do new things, you need to give it a push, and the more **Mass** it has, the more **Force** you’ll need to move (accelerate) it.

Inertia and **Mass** are equivalent concepts in physics:

“mass is the quantitative or numerical measure of a body's inertia, that is of its resistance to being accelerated”.

—Inertia, Wikipedia¹²

You could stop here and say that the more lines of code a project contains, the higher it’s mass. And, that makes sense, because in order to get it to do something new, you’re likely to need to change more lines.

But there is actually some underlying sense in which *this is real*, as discussed in this Veritasium¹³ video. To paraphrase:

“Most of your mass you owe due to $E=mc^2$, you owe to the fact that your mass is packed with energy, because of the **interactions** between these quarks and gluon fluctuations in the gluon field... what we think of as ordinarily empty space... that turns out to be the thing that gives us most of our mass.”

—Your Mass is NOT From the Higgs Boson, Veritasium¹⁴

I’m not an expert in physics, *at all*, and so there is every chance that I am pushing this analogy too hard. But, substituting quarks and gluons for pieces of software we can (in a very handwaving-y way) say that more complex software has more **interactions** going on, and therefore has more mass than simple software.

The reason I am labouring this analogy is to try and make the point that Complexity Risk is really fundamental:

- Feature Risk: like **money**.

¹¹https://en.wikipedia.org/wiki/Newton's_laws_of_motion

¹²https://en.wikipedia.org/wiki/Inertia#Mass_and_inertia

¹³<https://www.youtube.com/user/1veritasium>

¹⁴https://www.youtube.com/watch?annotation_id=annotation_3771848421&feature=iv&src_vid=Xo232kyTs00&v=Ztc6QPNuqls

- Schedule Risk: like **time**.
- Complexity Risk: like **mass**.

At a basic level, Complexity Risk: more complexity means you need more force to get things done, which takes longer.

12.7 Technical Debt

The most common way we talk about unnecessary complexity in software is as Technical Debt:

“Shipping first time code is like going into debt. A little debt speeds development so long as it is paid back promptly with a rewrite. . . The danger occurs when the debt is not repaid. Every minute spent on not-quite-right code counts as interest on that debt. Entire engineering organizations can be brought to a standstill under the debt load of an unconsolidated implementation, object-oriented or otherwise.”

Ward Cunningham, 1992¹⁵

Building a perfect first-time solution is a waste, because perfection takes a long time. You’re taking on more attendant Schedule Risk more slowly than you could.

A quick-and-dirty, over-complex implementation mitigates the same Feature Risk.

But, having mitigated the Feature Risk the software to reduce this risk again.

12.8 Kitchen Analogy

It's often hard to make the case for minimizing Technical Debt

One helpful analogy I have found is to imagine your code-base is a kitchen. After preparing a meal (i.e. delivering the first implementation), *you need to tidy up the kitchen*. This is just something everyone does as a matter of *basic sanitation*.

Now of course, you could carry on with the messy kitchen. When tomorrow comes and you need to make another meal, you find yourself needing to

¹⁵https://en.wikipedia.org/wiki/Technical_debt

wash up saucepans as you go, or working around the mess by using different surfaces to chop on.

It's not long before someone comes down with food poisoning.

We wouldn't tolerate this behaviour in a restaurant kitchen, so why put up with it in a software project?

12.9 Feature Creep

In Brooks' essay "No Silver Bullet - Essence and Accident in Software Engineering", a distinction is made between:

- **Essence:** *the difficulties inherent in the nature of the software.*
- **Accident:** *those difficulties that attend its production but are not inherent.* - Fred Brooks, *No Silver Bullet*¹⁶

The problem with this definition is that we are accepting features of our software as *essential*.

The **Risk-First** approach is that if you want to mitigate some Feature Risk as a result. But, that's a *choice you get to make*.

Therefore, Feature Creep¹⁷ (or Gold Plating¹⁸) is a failure to observe this basic equation: instead of considering this trade off, you're building every feature possible. This has an impact on Complexity Risk¹⁹, which in turn impacts Communication Risk²⁰ and also Schedule Risk²¹.

Sometimes, feature-creep happens because either managers feel they need to keep their staff busy, or the staff decide on their own that they need to keep themselves busy. But now, we can see that basically this boils down to bad risk management.

"Perfection is Achieved Not When There Is Nothing More to Add, But When There Is Nothing Left to Take Away"

Antoine de Saint-Exupery²²

- The risk that a particular approach to a change will fail.
Caused by the fact that at some level, our internal
models are not a complete reflection of reality.

Figure 12.5: Dead-End Risk

12.10 Dead-End Risk

Dead-End Risk is where you build functionality that you *think* is useful, only to find out later that actually, it was a dead-end, and is superceded by something else.

For example, let's say that the Accounting sub-system needed password protection (so you built this). Then the team realised that you needed a way to *change the password* (so you built that). Then, that you needed to have more than one user of the Accounting system so they would all need passwords (ok, fine).

Finally, the team realises that actually logging-in would be something that all the sub-systems would need, and that it had already been implemented more thoroughly by the Approvals sub-system.

At this point, you realise you're in a **Dead End**:

- **Option 1:** You carry on making minor incremental improvements to the accounting password system (carrying the extra Complexity Risk).
- **Option 2:** You rip out the accounting password system, and merge in the Approvals system, surfacing new, hidden Complexity Risk in the process, due to the difficulty in migrating users from the old to new way of working.
- **Option 3:** You start again, trying to take into account both sets of requirements at the same time, again, possibly surfacing new hidden Complexity Risk due to the combined approach.

¹⁹Complexity-Risk

²⁰Communication-Risk

²¹Schedule-Risk

²²

Sometimes, the path from your starting point to your goal on the Risk Landscape will take you to dead ends: places where the only way towards your destination is to lose something, and do it again another way.

This is because you surface new Hidden Risk in the solutions you choose. This happens a lot.

Source Control

Version Control Systems²³ like Git²⁴ are a useful mitigation of Dead-End Risk²⁵, because it means you can *go back* to the point where you made the bad decision and go a different way. Additionally, they provide you with backups against the often inadvertent Dead-End Risk²⁶ of someone wiping the hard-disk.

The Re-Write

Option 3, Rewriting code or a whole project can seem like a way to mitigate Complexity Risk, but it usually doesn't work out too well. As Joel Spolsky says:

There's a subtle reason that programmers always want to throw away the code and start over. The reason is that they think the old code is a mess. And here is the interesting observation: they are probably wrong. The reason that they think the old code is a mess is because of a cardinal, fundamental law of programming:
It's harder to read code than to write it. - Things You Should Never Do, Part 1, *Joel Spolsky*²⁷

The problem that Joel is outlining here is that the developer mistakes hard-to-understand code for unnecessary Complexity Risk.

12.11 Where Complexity Hides

Complexity isn't spread evenly within a software project. Some problems, some areas, have more than their fair share of issues. We're going to cover a few of these now, but be warned, this is not a complete list by any means:

- Memory Management
- Protocols / Types
- Algorithmic (Space and Time) Complexity
- Concurrency / Mutability
- Networks / Security

Memory Management

Memory Management is another place where Complexity Risk hides:

“Memory leaks are a common error in programming, especially when using languages that have no built in automatic garbage collection, such as C and C++.”

—Memory Leak, *Wikipedia*²⁸

Garbage Collectors²⁹ (as found in Javascript or Java) offer you the deal that they will mitigate the Complexity Risk³⁰ of you having to manage your own memory, but in return perhaps give you fewer guarantees about the *performance* of your software. Again, there are times when you can't accommodate this Operational Risk³¹, but these are rare and usually only affect a small portion of an entire software-system.

Protocols And Types

Whenever two components of a software system need to interact, they have to establish a protocol for doing so. There are lots of different ways this can work, but the simplest example I can think of is where some component **a** calls some function **b**. e.g:

```
function b(a, b, c) {
    return "whatever" // do something here.
}

function a() {
    var bOut = b("one", "two", "three");
    return "something "+bOut;
}
```

²⁸https://en.wikipedia.org/wiki/Memory_leak

²⁹[https://en.wikipedia.org/wiki/Garbage_collection_\(computer_science\)](https://en.wikipedia.org/wiki/Garbage_collection_(computer_science))

³⁰Complexity-Risk

³¹[Operational-Risk#performance-risk](#)

If component **b** then changes in some backwards-incompatible way, say:

```
function b(a, b, c, d /* new parameter */) {
    return "whatever" // do something here.
}
```

Then, we can say that the protocol has changed. This problem is so common, so endemic to computing that we've had compilers that check function arguments since the 1960's³². The point being is that it's totally possible for the compiler to warn you about when a protocol within the program has changed.

The same is basically true of Data Types³³: whenever we change the **Data Type**, we need to correct the usages of that type. Note above, I've given the javascript example, but I'm going to switch to typescript now:

```
interface BInput {
    a: string,
    b: string,
    c: string,
    d: string
}

function b(in: BInput): string {
    return "whatever" // do something here.
}
```

Now, of course, there is a tradeoff: we *mitigate* Complexity Risk.

Nevertheless, compilers and type-checking are so prevalent in software that clearly, you have to accept that in most cases, the trade-off has been worth it: Even languages like Clojure³⁴ have been retro-fitted with type checkers³⁵.

We're going to head into much more detail on this in the chapter on Protocol Risk.

³²<https://en.wikipedia.org/wiki/Compiler>

³³https://en.wikipedia.org/wiki/Data_type

³⁴<https://clojure.org>

³⁵<https://github.com/clojure/core.typed/wiki/User-Guide>

Space and Time Complexity

So far, we've looked at a couple of definitions of complexity in terms of the codebase itself. However, in Computer Science there is a whole branch of complexity theory devoted to how the software *runs*, namely Big O Complexity³⁶.

Once running, an algorithm or data structure will consume space or run-time dependent on its characteristics. As with Garbage Collectors³⁷, these characteristics can introduce Performance Risk³⁸ which can easily catch out the unwary. By and large, using off-the-shelf data structures and algorithms helps, but you still need to know their performance characteristics.

The Big O Cheatsheet³⁹ is a wonderful resource to investigate this further.

Concurrency / Mutability

Although modern languages include plenty of concurrency primitives, (such as the `java.util.concurrent`⁴⁰ libraries), concurrency is *still* hard to get right.

Race conditions⁴¹ and Deadlocks⁴² *thrive* in over-complicated concurrency designs: complexity issues are magnified by concurrency concerns, and are also hard to test and debug.

Recently, languages such as Clojure⁴³ have introduced persistent collections⁴⁴ to alleviate concurrency issues. The basic premise is that any time you want to *change* the contents of a collection, you get given back a *new collection*. So, any collection instance is immutable once created. The tradeoff is again attendant Performance Risk⁴⁵ to mitigate Complexity Risk⁴⁶.

An important lesson here is that choice of language can reduce complexity: and we'll come back to this in Software Dependency Risk.

Networking / Security

The last area I want to touch on here is networking. There are plenty of Complexity Risk.

⁴⁶[Complexity-Risk](#)

In the case of security considerations, exploits *thrive* on the complexity of your code, and the weaknesses that occur because of it. In particular, Schneier's Law says, never implement your own crypto scheme:

“Anyone, from the most clueless amateur to the best cryptographer, can create an algorithm that he himself can't break. It's not even hard. What is hard is creating an algorithm that no one else can break, even after years of analysis.”

Bruce Schneier, 1998⁴⁷

Luckily, most good languages include crypto libraries that you can include to mitigate these Complexity Risks from your own code-base.

This is a strong argument for the use of libraries. But, when should you use a library and when should you implement yourself? This is again covered in the chapter on Software Dependency Risk.

Communication Risk

Communication Risk is the risk of communication between entities *going wrong*, due to loss or misunderstanding. Consider this: if we all had identical knowledge, there would be no need to do any communicating at all, and therefore and also no Communication Risk.

But, people are not all-knowing oracles. We rely on our *senses* to improve our Internal Models.

Communication Risk isn't just for people; it affects computer systems too.

13.1 A Model Of Communication

In 1948, Claude Shannon proposed this definition of communication:

“The fundamental problem of communication is that of reproducing at one point, either exactly or approximately, a message selected at another point.”

—A Mathematical Theory Of Communication, *Claude Shannon*¹ <– tweet-end –>

And from this same paper, we get the following (slightly adapted) model.

We move from top-left (“I want to send a message to someone”) to bottom left, clockwise, where we hope the message has been understood and believed. (I’ve added this last box to Shannon’s original diagram.)

One of the chief concerns in Shannon’s paper is the step between **Transmission** and **Reception**. He creates a theory of information (measured in **bits**),

¹https://en.wikipedia.org/wiki/A_Mathematical_Theory_of_Communication

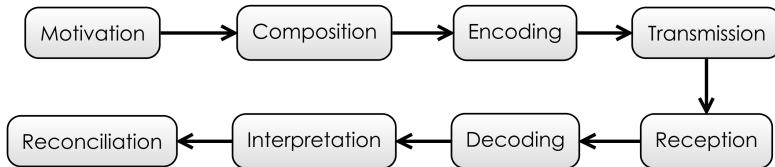

Figure 13.1: Shannon's Communication Model

the upper-bounds of information that can be communicated over a channel and ways in which Communication Risk between these processes can be mitigated by clever **Encoding** and **Decoding** steps.

But it's not just transmission. Communication Risk exists at each of these steps. Let's imagine a short exchange where someone, **Alice** is trying to send a message to **Bob**:

- Alice might be **motivated** to send a message to tell **Bob** something, only to find out that *he already knew it*, or it wasn't useful information for them.
- In the **composition** stage, Alice might mess up the *intent* of the message: instead of "Please buy chips" she might say, "Please buy chops".
- In the **encoding** stage, Alice might not speak clearly enough to be understood, and...
- In the **transmission** stage, Alice might not say it loudly enough for Bob to...
- **receive** the message clearly (maybe there is background noise).
- Having heard Alice say something, can Bob **decode** what was said into a meaningful sentence?
- Then, assuming that, will they **interpret** correctly which type of chips (or chops) Alice was talking about? Does "Please buy chips" convey all the information they need?
- Finally, assuming *everything else*, will Bob believe the message? Will they **reconcile** the information into their Internal Model and act on it? Perhaps not, if Bob thinks that there are chips at home already.

13.2 Approach To Communication Risk

There is a symmetry about the steps going on in Shannon's diagram, and we're going to exploit this in order to break down Communication Risk into its main types.

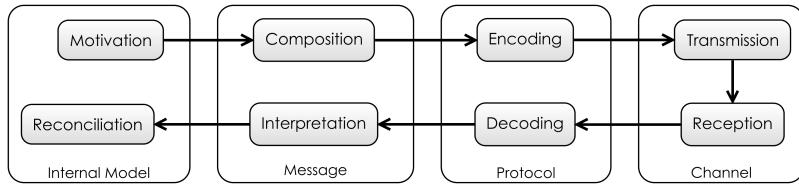

Figure 13.2: Communication Risk 2

To get inside Communication Risk, we need to understand **Communication** itself, whether between *machines, people or products*: we'll look at each in turn. In order to do that, we're going to examine four basic concepts in each of these settings:

- Channels², the medium via which the communication is happening.
- Protocols³ - the systems of rules that allow two or more entities of a communications system to transmit information.
- Messages⁴: The information we want to convey.
- Internal Models is the reason why we're communicating.

And, as we look at these four areas, we'll consider the Attendant Risks of each.

13.3 Channels

There are lots of different types of media for communicating (e.g. TV, Radio, DVD, Talking, Posters, Books, Phones, The Internet, etc.) and they all have different characteristics. When we communicate via a given medium, it's called a *channel*.

The channel *characteristics* depend on the medium, then. Some obvious ones are cost, utilisation, number of people reached, simplex or duplex (parties can transmit and receive at the same time), persistence (a play vs a book, say), latency (how long messages take to arrive) and bandwidth (the amount of information that can be transmitted in a period of time).

Channel characteristics are important: in a high-bandwidth, low-latency situation, **Alice** and **Bob** can *check* with each other that the meaning was

²https://en.wikipedia.org/wiki/Communication_channel

³https://en.wikipedia.org/wiki/Communication_protocol

⁴<https://en.wikipedia.org/wiki/Message>

transferred correctly. They can discuss what to buy, they can agree that Alice wasn't lying or playing a joke.

The channel characteristics also imply suitability for certain *kinds* of messages. A documentary might be a great way of explaining some economic concept, whereas an opera might not be.

13.4 Channel Risk

Shannon discusses that no channel is perfect: there is always the **risk of noise** corrupting the signal. A key outcome from Shannon's paper is that there is a tradeoff: within the capacity of the channel (the **Bandwidth**), you can either send lots of information with *higher* risk that it is wrong, or less information with *lower* risk of errors. And, rather like the Kolgomorov complexity result, the more *randomness* in the signal, the less compressible it is, and therefore the more *bits* it will take to transmit.

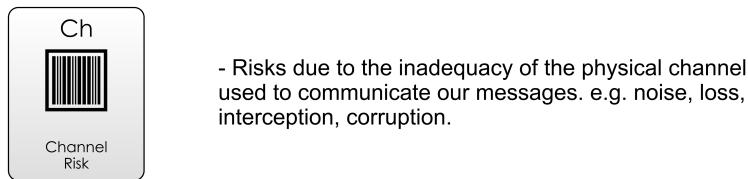

Figure 13.3: Communication Channel Risk

But channel risk goes wider than just this mathematical example: messages might be delayed or delivered in the wrong order, or not be acknowledged when they do arrive. Sometimes, a channel is just an inappropriate way of communicating. When you work in a different time-zone to someone else on your team, there is *automatic* Channel Risk, because instantaneous communication is only available for a few hours' a day.

When channels are **poor-quality**, less communication occurs. People will try to communicate just the most important information. But, it's often impossible to know a-priori what constitutes "important". This is why Extreme Programming by ensuring high-quality communication channels are in place.

At other times, channels can contain so much information that we can't hope to receive all the messages. In these cases, we don't even observe the whole channel, just parts of it. For example, you might have a few YouTube channels

that you subscribe to, but hundreds of hours of video are being posted on YouTube every second, so there is no way you can keep up with all of it.

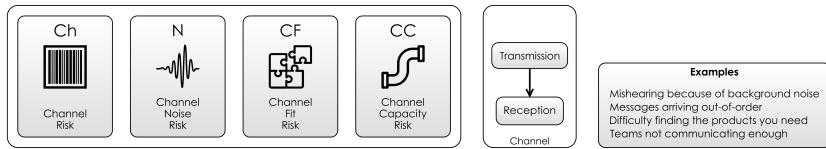

Figure 13.4: Communication Channels

Marketing Communications

When we are talking about a product or a brand, mitigating Channel Risk⁵ is the domain of Marketing Communications⁶. How do you ensure that the information about your (useful) project makes it to the right people? How do you address the right channels?

This works both ways. Let's look at some of the **Channel Risks** from the point of view of a hypothetical software tool, **D**, which would really useful in my software:

- The concept that there is such a thing as **D** which solves my problem isn't something I'd even considered.
- I'd like to use something like **D**, but how do I find it?
- There are multiple implementations of **D**, which is the best one for the task?
- I know **D**, but I can't figure out how to solve my problem in it.
- I've chosen **D**, I now need to persuade my team that **D** is the correct solution...
- ... and then they also need to understand **D** to do their job too.

Internal Models when needed.

13.5 Protocols

In this chapter, I want to examine the concept of Communication Protocols⁷ and how they relate to Abstraction⁸.

⁵[Communication-Risk#channel-risk](#)

⁶https://en.wikipedia.org/wiki/Marketing_communications

⁷https://en.wikipedia.org/wiki/Communication_protocol

⁸[Glossary#abstraction](#)

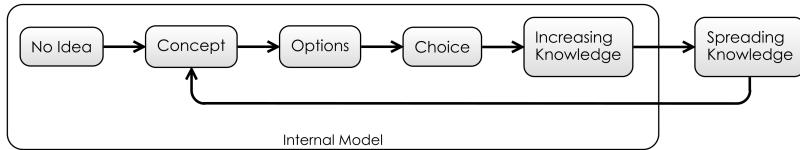

Figure 13.5: Communication Marketing

So, to do this, let's look in a bit of detail at how web pages are loaded. When considering this, we need to broaden our terminology. Although so far we've talked about **Senders** and **Receivers**, we now need to talk from the point of view of who-depends-on-who. If you're *depended on*, then you're a "Server", whereas if you require communication with something else, you're a "Client". Thus, clients depend on servers in order to load pages.

This is going to involve (at least) six separate protocols, the top-most one being the HTTP Protocol⁹. As far as the HTTP Protocol is concerned, a *client* makes an **HTTP Request** at a specific URL and the **HTTP Response** is returned in a predictable format that the browser can understand.

Let's have a quick look at how that works with a `curl` command, which allows me to load a web page from the command line. We're going to try and load Google's preferences page, and see what happens. If I type:

```
> curl -v http://google.com/preferences
```

1. DNS - Domain Name System

Then, the first thing that happens is this:

```
* Rebuilt URL to: http://google.com/
* Trying 216.58.204.78...
```

At this point, `curl` has used DNS¹⁰ to *resolve* the address "google.com" to an IP address. This is some Abstraction¹¹: instead of using the machine's IP Address¹² on the network, 216.58.204.78, I can use a human-readable address, `google.com`. The address `google.com` doesn't necessarily resolve to

⁹https://en.wikipedia.org/wiki/Hypertext_Transfer_Protocol

¹⁰https://en.wikipedia.org/wiki/Domain_Name_System

¹¹[Glossary#abstraction](#)

¹²https://en.wikipedia.org/wiki/IP_address

that same address each time: *They have multiple IP addresses for google.com.* But, for the rest of the curl request, I'm now set to just use this one.

2. IP - Internet Protocol

But this hints at what is beneath the abstraction: although I'm loading a web-page, the communication to the Google server happens by IP Protocol¹³ - it's a bunch of discrete "packets" (streams of binary digits). You can think of a packet as being like a real-world parcel or letter.

Each packet consists of two things:

- An address, which tells the network components (such as routers and gateways) where to send the packet, much like you'd write the address on the outside of a parcel.
- The *payload*, the stream of bytes for processing at the destination. Like the contents of the parcel.

But, even this concept of "packets" is an Abstraction. Although all the components of the network interoperate with this protocol, we might be using Wired Ethernet, or WiFi, 4G or *something else*.

3. 802.11 - WiFi Protocol

I ran this at home, using WiFi, which uses IEEE 802.11 Protocol¹⁴, which allows my laptop to communicate with the router wirelessly, again using an agreed, standard protocol. But even *this isn't the bottom*, because this is actually probably specifying something like MIMO-OFDM¹⁵, giving specifications about frequencies of microwave radiation, antennas, multiplexing, error-correction codes and so on. And WiFi is just the first hop: after the WiFi receiver, there will be protocols for delivering the packets via the telephony system.

4. TCP - Transmission Control Protocol

Anyway, the next thing that happens is this:

```
* TCP_NODELAY set
* Connected to google.com (216.58.204.78) port 80 (#0)
```

¹³https://en.wikipedia.org/wiki/Internet_Protocol

¹⁴https://en.wikipedia.org/wiki/IEEE_802.11

¹⁵<https://en.wikipedia.org/wiki/MIMO-OFDM>

The second obvious Abstraction¹⁶ going on here is that curl now believes it has a TCP¹⁷ connection. The TCP connection abstraction gives us the surety that the packets get delivered in the right order, and retried if they go missing. Effectively it *guarantees* these things, or that it will have a connection failure if it can't keep its guarantee.

But, this is a fiction - TCP is built on the IP protocol, packets of data on the network. So there are lots of packets floating around which say "this connection is still alive" and "I'm message 5 in the sequence" and so on in order to maintain this fiction. But that means that the HTTP protocol can forget about this complexity and work with the fiction of a connection.

5. HTTP - Hypertext Transfer Protocol

Next, we see this:

```
> GET /preferences HTTP/1.1      (1)
> Host: google.com              (2)
> User-Agent: curl/7.54.0       (3)
> Accept: */*                   (4)
>                               (5)
```

This is now the HTTP protocol proper, and these 5 lines are sending information *over the connection* to the Google server.

- (1) says what version of HTTP we are using, and the path we're loading (`/preferences` in this case).
- (2) to (4) are *headers*. They are name-value pairs, separated with a colon. The HTTP protocol specifies a bunch of these names, and later versions of the protocol might introduce newer ones.
- (5) is an empty line, which indicates that we're done with the headers, please give us the response. And it does:

```
< HTTP/1.1 301 Moved Permanently
< Location: http://www.google.com/preferences
< Content-Type: text/html; charset=UTF-8
< Date: Sun, 08 Apr 2018 10:24:34 GMT
< Expires: Tue, 08 May 2018 10:24:34 GMT
< Cache-Control: public, max-age=2592000
```

¹⁶Glossary#abstraction

¹⁷https://en.wikipedia.org/wiki/Transmission_Control_Protocol

```

< Server: gws
< Content-Length: 230
< X-XSS-Protection: 1; mode=block
< X-Frame-Options: SAMEORIGIN
<
<HTML><HEAD><meta http-equiv="content-type"
content="text/html; charset=utf-8">
<TITLE>301 Moved</TITLE></HEAD><BODY>
<H1>301 Moved</H1>
The document has moved
</BODY></HTML>
* Connection #0 to host google.com left intact

```

There's a lot going on here, but we can break it down really easily into 3 chunks:

1. The first line is the HTTP Status Code¹⁸. 301 is a code meaning that the page has moved.
2. The next 9 lines are HTTP headers again (name-value pairs). The Location: directive tells us where the page has moved to. Instead of trying `http://google.com/preferences`, we should have used:

`http://www.google.com/preferences.`

3. The lines starting <HTML> are now some HTML to display on the screen to tell the user that the page has moved.

6. HTML - Hypertext Markup Language

Although HTML¹⁹ is a language, a language is also a protocol. (After all, language is what we use to encode our ideas for transmission as speech.) In the example we gave, this was a very simple page telling the client that it's looking in the wrong place. In most browsers, you don't get to see this: the browser will understand the meaning of the 301 error and redirect you to the location.

Let's look at all the protocols we saw here:

¹⁸https://en.wikipedia.org/wiki/List_of_HTTP_status_codes

¹⁹<https://en.wikipedia.org/wiki/HTML>

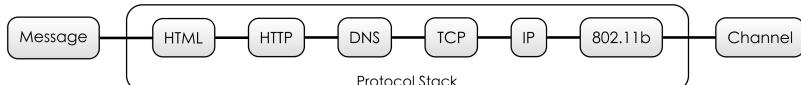

Figure 13.6: Protocol Stack

Each protocol “passes on” to the next one in the chain. On the left, we have the representation most suitable for the *messages*: HTTP is designed for browsers to use to ask for and receive web pages. As we move right, we are converting the message more and more into a form suitable for the Channel: in this case, microwave transmission.

By having a stack of protocols, we are able to apply Separation Of Concerns²⁰, each protocol handling just a few concerns:

- HTML Abstraction: A language for describing the contents of a web-page.
- HTTP Abstraction: Name-Value pairs, agreed on by both curl and Google, URLs and error codes.
- DNS Abstraction: Names of servers to IP Addresses.
- TCP Abstraction: The concept of a “connection” with guarantees about ordering and delivery.
- IP Abstraction: “Packets” with addresses and payloads.
- WiFi Abstraction: “Networks”, 802.11 flavours.
- Transmitters, Antennas, error correction codes, etc.

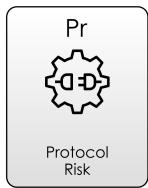

HTTP “stands on the shoulders of giants”. Not only does it get to use pre-existing protocols like TCP and DNS to make it’s life easier, it got 802.11 “for free” when this came along and plugged into the existing IP protocol. This is the key value of abstraction: you get to piggy-back on *existing* patterns, and use them yourself.

The protocol mediates between the message and the channel. Where this goes wrong, we have Protocol Risk. This is a really common issue for IT systems, but also sometimes for human communication too.

13.6 Protocol Risk

Generally, any time where you have different parts of a system communicating with each other, and one part can change incompatibly with another you have Protocol Risk.

²⁰https://en.wikipedia.org/wiki/Separation_of_concerns

- Risks due to the failure of encoding or decoding messages between two parties in communication.

Figure 13.7: Protocol Risk

Locally, (within our own project), where we have control, we can mitigate this risk using compile-time checking (as discussed already in Complexity Risk).

Let's look at some types of Protocol Risk:

Protocol Incompatibility Risk

The people you find it *easiest* to communicate with are your friends and family, those closest to you. That's because you're all familiar with the same protocols. Someone from a foreign country, speaking a different language and having a different culture, will essentially have a completely incompatible protocol for spoken communication to you.

Within software, there are also competing, incompatible protocols for the same things, which is maddening when your protocol isn't supported. Although the world seems to be standardizing, there used to be *hundreds* of different image formats. Photographs often use TIFF²¹, RAW²² or JPEG²³, whilst we also have SVG²⁴ for vector graphics, GIF²⁵ for images and animations and PNG²⁶ for other bitmap graphics.

Protocol Versioning Risk

Even when systems are talking the same protocol, there can be problems. When we have multiple, different systems owned by different parties, on their own upgrade cycles, we have **Protocol Versioning Risk**: the risk that either client or server could start talking in a version of the protocol that the other

²¹<https://en.wikipedia.org/wiki/TIFF>

²²https://en.wikipedia.org/wiki/Raw_image_format

²³<https://en.wikipedia.org/wiki/JPEG>

²⁴https://en.wikipedia.org/wiki/Scalable_Vector_Graphics

²⁵<https://en.wikipedia.org/wiki/GIF>

²⁶https://en.wikipedia.org/wiki/Portable_Network_Graphics

side hasn't learnt yet. There are various mitigating strategies for this. We'll look at two now: **Backwards Compatibility** and **Forwards Compatibility**.

Protocol Complexity

tbd. abstraction - virtue between two vices. Postel's law.

Backward Compatibility

Backwards Compatibility mitigates Protocol Versioning Risk²⁷. Quite simply, this means, supporting the old format until it falls out of use. If a server is pushing for a change in protocol it either must ensure that it is Backwards Compatible with the clients it is communicating with, or make sure they are upgraded concurrently. When building web services²⁸, for example, it's common practice to version all APIs so that you can manage the migration. Something like this:

- Server publishes /api/v1/something.
- Clients use /api/v1/something.
- Server publishes /api/v2/something.
- Clients start using /api/v2/something.
- Clients (eventually) stop using /api/v2/something.
- Server retires /api/v2/something API.

Forward Compatibility

HTML and HTTP provide "graceful failure" to mitigate Protocol Risk: while its expected that all clients can parse the syntax of HTML and HTTP, it's not necessary for them to be able to handle all of the tags, attributes and rules they see. The specification for both these standards is that if you don't understand something, ignore it. Designing with this in mind means that old clients can always at least cope with new features, but it's not always possible.

JavaScript *can't* support this: because the meaning of the next instruction will often depend on the result of the previous one.

Does human language support this? To some extent! New words are added to our languages all the time. When we come across a new word, we can either ignore it, guess the meaning, ask or look it up. In this way, human language has **Forward Compatibility** features built in.

²⁸https://en.wikipedia.org/wiki/Web_service

Protocol Implementation Risk

A second aspect of Protocol Risk as possible, generally we run tests in a subset of browsers, and use a lowest-common-denominator approach to choosing protocol and language features.

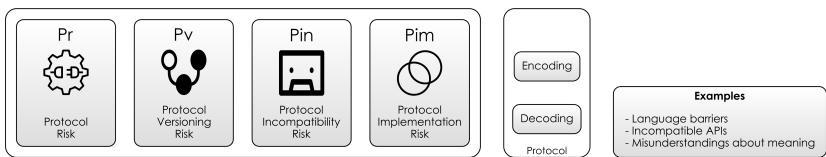

Figure 13.8: Communication Protocols Risks

13.7 Messages

- Risks caused by the difficulty of composing and interpreting messages in the communication process.

Figure 13.9: Message Risk

Although Shannon's Communication Theory is about transmitting **Messages**, messages are really encoded **Ideas** and **Concepts**, from an **Internal Model**.

Internal Model Assumption Risk

When we construct messages in a conversation, we have to make judgements about what the other person already knows. When talking to children, it's often hard work because they *assume* that you have knowledge of everything they do. This is called Theory Of Mind²⁹: the appreciation that your knowledge is different to other people's, and adjusting your messages accordingly.

When teaching, this is called The Curse Of Knowledge³⁰: teachers have difficulty understanding students' problems *because they already understand*

²⁹https://en.wikipedia.org/wiki/Theory_of_mind

³⁰https://en.wikipedia.org/wiki/Curse_of_knowledge

the subject. For example, if I want to tell you about a new JDBC Driver³¹, this pre-assumes that you know what JDBC is: the message has a dependency on prior knowledge.

Message Dependency Risk

A second, related problem is actually Dependency Risk will not be rich enough to understand the new messages.

This happens when messages get missed, or delivered out of order. In the past, TV shows were only aired once a week at a particular time. So writers were constrained plot-wise by not knowing whether their audience would have seen the previous week's episode. Therefore, often the state of the show would "reset" week-to-week, allowing you to watch it in *any* order.

The same **Message Dependency Risk** exists for computer software: if there is replication going on between instances of an application, and one of the instances misses some messages, you end up with a "Split Brain"³² scenario, where later messages can't be processed because they refer to an application state that doesn't exist. For example, a message saying:

```
Update user 53's surname to 'Jones'
```

only makes sense if the application has previously had the message

```
Create user 53 with surname 'Smith'
```

Misinterpretation Risk

People don't rely on rigorous implementations of abstractions like computers do; we make do with fuzzy definitions of concepts and ideas. We rely on Abstraction to move between the name of a thing and the *idea of a thing*.

While machines only process *information*, people's brains run on concepts and ideas. For people, abstraction is critical: nothing exists unless we have a name for it. Our world is just atoms, but we don't think like this. *The name is the thing.*

"The famous pipe. How people reproached me for it! And yet, could you stuff my pipe? No, it's just a representation, is it

³¹https://en.wikipedia.org/wiki/JDBC_driver

³²[https://en.wikipedia.org/wiki/Split-brain_\(computing\)](https://en.wikipedia.org/wiki/Split-brain_(computing))

not? So if I had written on my picture "This is a pipe", I'd have been lying!"

—Rene Magritte, of *The Treachery of Images*³³

This brings about Misinterpretation Risk: names are not *precise*, and concepts mean different things to different people. We can't be sure that people have the same meaning for concepts that we have.

Invisibility Risk

Another cost of Abstraction it lets the function of a thing hide behind the layers of abstraction and become invisible.

Invisibility Risk In Software

As soon as you create a function, you are doing abstraction. You are saying: "I now have this operation. The details, I won't mention again, but from now on, it's called **f**" And suddenly, "**f**" hides. It is working invisibly. Things go on in **f** that people don't necessarily need to understand. There may be some documentation, or tacit knowledge around what **f** is, and what it does, but it's not necessarily right. Referring to **f** is a much simpler job than understanding **f**.

We try to mitigate this via (for the most part) documentation, but this is a terrible deal: because we can't understand the original, (un-abstracted) implementation, we now need to write some simpler documentation, which *explains* the abstraction, in terms of further abstractions, and this is where things start to get murky.

Invisibility Risk But you can carelessly *hide things from yourself* with software:

- Adding a thread to an application that doesn't report whether it's worked, failed, or is running out of control and consuming all the cycles of the CPU.
- Redundancy can increase reliability, but only if you know when servers fail, and fix them quickly. Otherwise, you only see problems when the last server fails.
- When building a webservice, can you assume that it's working for the users in the way you want it to?

When you build a software service, or even implement a thread, ask yourself: "How will I know next week that this is working properly?" If the answer

³³https://en.wikipedia.org/wiki/The_Treachery_of_Images

involves manual work and investigation, then your implementation has just cost you in Invisibility Risk.

Invisibility Risk In Conversation

Invisibility Risk in communication, and this saves us time when we're talking. It would be *painful* to have conversations if, say, the other person needed to understand everything about how cars worked in order to discuss cars.

For people, Abstraction is a tool that we can use to refer to other concepts, without necessarily knowing how the concepts work. This divorcing of "what" from "how" is the essence of abstraction and is what makes language useful.

The debt of Invisibility Risk comes due when you realise that *not* being given the details *prevents* you from reasoning about it effectively. Let's think about this in the context of a project status meeting, for example:

- Can you be sure that the status update contains all the details you need to know?
- Is the person giving the update wrong or lying?
- Do you know enough about the details of what's being discussed in order to make informed decisions about how the project is going?

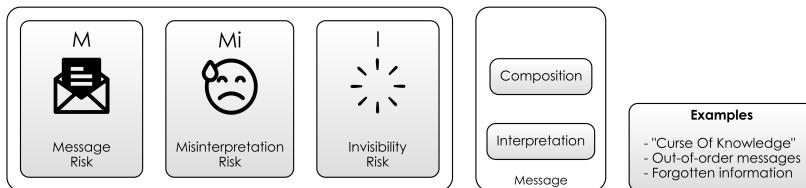

Figure 13.10: Message Risk

13.8 Internal Models

So finally, we are coming to the root of the problem: communication is about transferring ideas and concepts from one Internal Model to another.

The communication process so far has been fraught with risks, but we have a few more to come.

Trust & Belief Risk

Although protocols can sometimes handle security features of communication (such as Authentication³⁴ and preventing man-in-the-middle attacks³⁵), trust goes further than this, intersecting with Agency Risk³⁶: can you be sure that the other party in the communication is acting in your best interests?

Even if the receiver trusts the communicator, they may not trust the message. Let's look at some reasons for that:

- Weltanschauung (World View)³⁷: The ethics, values and beliefs in the receiver's Internal Model³⁸ may be incompatible to those from the sender.
- Relativism³⁹ is the concept that there are no universal truths. Every truth is from a frame of reference. For example, what constitutes *offensive language* is dependent on the listener.
- Psycholinguistics⁴⁰ is the study of humans acquire languages. There are different languages and dialects, (and *industry dialects*), and we all understand language in different ways, take different meanings and apply different contexts to the messages.

From the point-of-view of Marketing Communications.

Reputational Risk

tbd.

Learning-Curve Risk

If the messages we are receiving force us to update our Internal Model⁴¹ too much, we can suffer from the problem of "too steep a Learning Curve⁴²" or "Information Overload⁴³", where the messages force us to adapt our Internal Model⁴⁴ too quickly for our brains to keep up.

⁴⁴Glossary#Internal-Model

Commonly, the easiest option is just to ignore the information channel completely in these cases.

Reading Code

It's often been said that code is *harder to read than to write*:

If you ask a software developer what they spend their time doing, they'll tell you that they spend most of their time writing code. However, if you actually observe what software developers spend their time doing, you'll find that they spend most of their time trying to understand code.

By now it should be clear that it's going to be *both* quite hard to read and write: the protocol of code is actually designed for the purpose of machines communicating, not primarily for people to understand. Making code human readable is a secondary concern to making it machine readable.

But now we should be able to see the reasons it's harder to read than write too:

- When reading code, you are having to shift your Internal Model⁴⁵ to wherever the code is, accepting decisions that you might not agree with and accepting counter-intuitive logical leaps. i.e. Learning Curve Risk⁴⁶. (*cf. Principle of Least Surprise*⁴⁷)
- There is no Feedback Loop. When you write code, your compiler and tests give you this.
- While reading code *takes less time* than writing it, this also means the Learning Curve is steeper.

13.9 Communication Risk Wrap Up

So, here's a summary of where we've arrived with our model of communication risk:

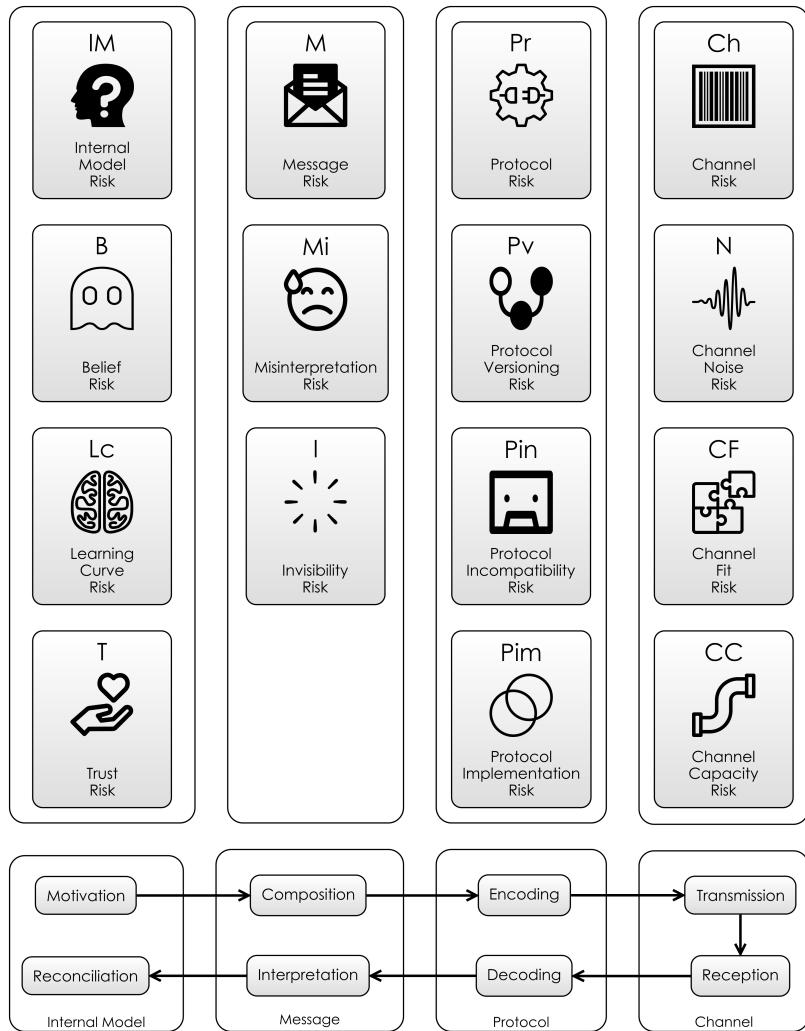

Figure 13.12: Communication 2

There's no point to Communication unless you have someone or something to communicate with! So next it's time to look at Dependency Risk.
this seems complex tbd.

Dependency Risk

Dependency Risk else. One simple example could be that the software service you write might depend on a server to run on. If the server goes down, the service goes down too. In turn, the server depends on electricity from a supplier, as well as a network connection from a provider. If either of these dependencies aren't met, the service is out of commission.

Dependencies can be on *events, people, teams, processes, software, services, money*: pretty much *any resource*. Dependencies add risk to any project because the reliability of the project itself is now a function involving the reliability of the dependency.

In order to avoid repetition, and also to break down this large topic, we're going to look at this over 6 chapters:

- In this first chapter will look at dependencies *in general*, and specifically on *events*, and some of the variations on Dependency Risk.
- Next, we'll look at Schedule Risk, because time and money are key dependencies in any project.
- Then, we'll move on to look specifically at Software Dependency Risk, covering using libraries, software services and building on top of the work of others.
- After, we'll take a look at Process Risk, but we'll be considering more organisational factors and how bureaucracy comes into the picture.
- Next, we'll take a closer look at Boundary Risk. These are the risks you face in choosing the wrong things to depend on.
- Finally, we'll wrap up this analysis with a look at some of the specific problems around working with other people or businesses in Agency Risk.

14.1 Why Have Dependencies?

Luckily for us, the things we depend on in life are, for the most part, abundant: water to drink, air to breathe, light, heat and most of the time, food for energy.

This isn't even lucky though: life has adapted to build dependencies on things that it can *rely* on.

Although life exists at the bottom of the ocean around hydrothermal vents¹, it is a very different kind of life to us, and has a different set of dependencies given it's circumstances.

This tells us a lot about Dependency Risk right here:

- On the one hand, depending on something else is very often helpful, and quite often essential. (For example, all animals that *move* seem to depend on oxygen).
- However, as soon as you have dependencies, you need to take into account of their *reliability*. (Living near a river or stream gives you access to fresh water, for example).
- Successful organisms *adapt* to the dependencies available to them (like the thermal vent creatures).
- There is likely to be *competition* for a dependency when it is scarce (think of droughts and famine).

So, dependencies are a trade-off. They give with one hand and take with the other. Our modern lives are full of dependency (just think of the chains of dependency needed for putting a packet of biscuits on a supermarket shelf, for example), but we accept this extra complexity because it makes life *easier*.

14.2 Simple Made Easy

In Rich Hickey's talk, Simple Made Easy² he discusses the difference between *simple* software systems and *easy* (to use) ones, heavily stressing the virtues of simple over easy. It's an incredible talk and well worth watching.

But. Living systems are not simple. Not anymore. They evolved in the direction of increasing complexity because life was *easier* that way. In the "simpler" direction, life is first *harder* and then *impossible*, and then an evolutionary dead-end.

¹https://en.wikipedia.org/wiki/Hydrothermal_vent

²<https://www.infoq.com/presentations/Simple-Made-Easy>

Depending on things makes *your job easier*. It's just division of labour³ and dependency hierarchies, as we saw in Hierarchies and Modularization⁴.

Our economic system and our software systems exhibit the same tendency-towards-complexity. For example, the television in my house now is *vastly more complicated* than the one in my home when I was a child. But, it contains much more functionality and consumes much less power and space.

14.3 Event Dependencies

Let's start with dependencies on *events*.

We rely on events occurring all the time in our lives, and so this is a good place to start in our analysis of Dependency Risk generally. And, as we will see, all the risks that apply to events pretty much apply to all the other kinds of dependencies we'll look at.

Arguably, the event dependencies are the simplest to express, too: usually, a *time* and a *place*. For example: - "I can't start shopping until the supermarket opens at 9am", or - "I must catch my bus to work at 7:30am".

In the first example, you can't *start* something until a particular event happens. In the latter example, you must *be ready* for an event at a particular time.

Events Mitigate Risk...

Having an event occur in a fixed time and place is mitigating risk:

- By taking the bus, we are mitigating our own Schedule Risk reducing the amount of time we're going to spend on the activity of getting to work.
- Events are a mitigation for Coordination Risk. Agreeing a date for a product launch, for example, allows lots of teams to coordinate their activities.
- It's not entirely necessary to even take the bus: you could walk, or go by another form of transport. But, effectively, this just swaps one dependency for another: if you walk, this might well take longer and use more energy, so you're just picking up Schedule Risk on a different scarce resource - your money.

³https://en.wikipedia.org/wiki/Division_of_labour

⁴[Complexity-Risk#Hierarchies-and-Modularization](#)

But, Events Lead To Attendant Risk

By deciding to use the bus we've Taken Action.

Figure 14.1: Action Diagram showing risks mitigated by having an event

However, as we saw in A Simple Scenario.

So, we're going to look at Dependency Risk from 7 different perspectives, many of which we've already touched on in the other chapters.

- Schedule Risk
- Reliability Risk
- Scarcity Risk
- Communication Risk
- Complexity Risk
- Feature Fit Risk
- Dead-End Risk

(Although you might be able to think of a few more.)

Let's look at each of these in turn.

14.4 Schedule Risk

By agreeing a *time* and *place* for something to happen, you're introducing Deadline Risk. Miss the deadline, and you miss the bus, or the start of the meeting or get fined for not filling your tax return on time.

As discussed above, *schedules* (such as bus timetables) exist so that *two or more parties can coordinate*, and Deadline Risk is on *all* of the parties. While there's a risk I am late, there's also a risk the bus is late. I might miss the start of a concert, or the band might keep everyone waiting.

Each party can mitigate Deadline Risk with *slack*. That is, ensuring that the exact time of the event isn't critical to your plans:

- The aspect of dependency risk related to time.

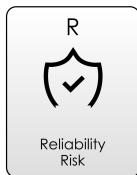

Figure 14.2: Schedule Risk

- Don't build into your plans a *need* to start shopping at 9am.
- Arrive at the bus-stop *early*.

The amount of slack you build into the schedule is likely dependent on the level of risk you face: I tend to arrive a few minutes early for a bus, because the risk is *low* (there'll be another bus along soon), however I try to arrive over an hour early for a flight, because I can't simply get on the next flight straight away, and I've already paid for it, so the risk is *high*.

Deadline Risk becomes very hard to manage when you have to coordinate actions with lots of tightly-constrained events. So what else can give? We can reduce the number of *parties* involved in the event, which reduces risk, or, we can make sure all the parties are in the same *place* to begin with.

14.5 Reliability Risk

- Risks of not getting benefit from a dependency due to its reliability.

Figure 14.3: Reliability Risk

Deadline Risk.

Luckily, there is quite a lot of existing science around reliability. For example:

- If a component **A** depends on component **B**, unless there is some extra redundancy around **B**, then **A** *can't* be more reliable than **B**.
- Is **A** or **B** a Single Point Of Failure⁵ in a system?
- Are there bugs in **B** that are going to prevent it working correctly in all circumstances?

This kind of stuff is encapsulated in the science of Reliability Engineering⁶. For example, Failure mode and effects analysis (FEMA)⁷:

“...was one of the first highly structured, systematic techniques for failure analysis. It was developed by reliability engineers in the late 1950s to study problems that might arise from malfunctions of military systems.”

—FEMA, Wikipedia⁸

This was applied on NASA missions, and then more recently in the 1970's to car design following the Ford Pinto exploding car⁹ affair.

14.6 Scarcity Risk

- Risk of not being able to access a dependency in a timely fashion due to its scarcity.

Figure 14.4: Scarcity Risk

Let's get back to the bus (which, hopefully, is still working). What if, when it arrives, it's already full of passengers? Let's term this, Scarcity Risk - the chance that a dependency is over-subscribed and you can't use it the way you want. This is clearly an issue for nearly every kind of dependency: buses, supermarkets, concerts, teams, services and people.

⁸https://en.wikipedia.org/wiki/Failure_mode_and_effects_analysis

⁹https://en.wikipedia.org/wiki/Ford_Pinto#Design_flaws_and_ensuing_lawsuits

You could also call this *availability risk* or *capacity risk* of the resource. Here are a selection of mitigations:

- **Buffers:** Smoothing out peaks and troughs in utilisation.
- **Reservation Systems:** giving clients information *ahead* of the dependency usage about whether the resource will be available to them.
- **Graceful degradation:** Ensuring *some* service in the event of over-subscription. It would be no use allowing people to cram onto the bus until it can't move.
- **Demand Management:** Having different prices during busy periods helps to reduce demand. Having "first class" seats means that higher-paying clients can get service even when the train is full. Uber¹⁰ adjust prices in real-time by so-called Surge Pricing¹¹. This is basically turning Scarcity Risk¹² into a Market Risk¹³ problem.
- **Queues:** Again, these provide a "fair" way of dealing with scarcity by exposing some mechanism for prioritising use of the resource. Buses operate a first-come-first-served system, whereas emergency departments in hospitals triage according to need.
- **Pools:** Reserving parts of a resource for particular customers.
- **Horizontal Scaling:** allowing a scarce resource to flexibly scale according to how much demand there is. (For example, putting on extra buses when the trains are on strike, or opening extra check-outs at the supermarket.)

Much like Reliability Risk, there is science for it:

- Queue Theory¹⁴ is all about building mathematical models of buffers, queues, pools and so forth.
- Logistics¹⁵ is the practical organisation of the flows of materials and goods around things like Supply Chains¹⁶.
- And Project Management¹⁷ is in large part about ensuring the right resources are available at the right times. We'll be taking a closer look at that in the Part 3 chapters on Prioritisation and the Project Management Body Of Knowledge¹⁸.

14.7 Communication Risk

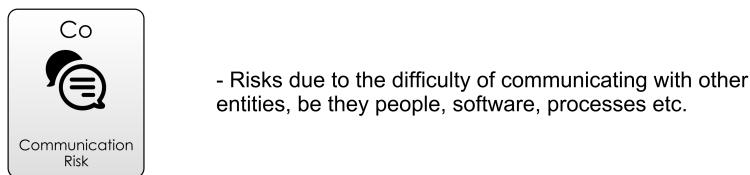

Figure 14.5: Communication Risk

We've already looked at communication risk in a lot of depth, and we're going to go deeper still in Software Dependency Risk and talked about the levels of awareness that you could have with dependencies. i.e.

- The concept that there is such a thing as D which solves my problem isn't something I'd even considered.
- I'd like to use something like D, but how do I find it?
- There are multiple implementations of D, which is the best one for the task?
- I know D, but I can't figure out how to solve my problem in it.

Let's apply this to our Bus scenario:

- Am I aware that there is public transport in my area?
- How do I find out about the different options?
- How do I choose between buses, taxis, cars etc.
- How do I understand the timetable, and apply it to my problem?

Silo Mentality

Finding out about bus schedules is easy. But in a large company, Communication Risk¹⁹ and especially Invisibility Risk²⁰ are huge problems. This tends to get called "Silo Mentality"²¹, that is, ignoring what else is going on in other divisions of the company or "not invented here"²² syndrome:

¹⁹Communication-Risk

²⁰Communication-Risk#invisibility-risk

²¹https://en.wikipedia.org/wiki/Information_silo#Silo_mentality

²²https://en.wikipedia.org/wiki/Not_invented_here

“In management the term silo mentality often refers to information silos in organizations. Silo mentality is caused by divergent goals of different organizational units.”

—Silo Mentality, Wikipedia²³

Ironically, *more communication* might not be the answer - if channels are provided to discover functionality in other teams you can still run into Trust Risk in terms of too low a signal-to-noise ratio, or desperate self-promotion.

Silo Mentality is exacerbated by the problems you would face in *budgeting* if suddenly all the divisions in an organisation started providing dependencies for each other. This starts to require a change to organisational structure towards being a set of individual businesses marketing services to one another, rather than a division-based one. We'll look more closely at these kind of organisational issues in the Coordination Risk chapter.

14.8 Complexity Risk

Dependencies are usually a mitigation for Complexity Risk, you just need to interact with the dependency properly to get the job done. Buses are *perfect* for people who can't drive, after all.

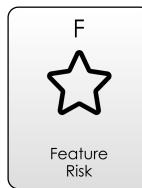

But this means that all of the issues of abstractions that we covered in Communication Risk apply:

- There is Invisibility Risk because you probably don't have a full view of what the dependency is doing. Nowadays, bus stops have a digital “arrivals” board which gives you details of when the bus will arrive, and shops publish their opening hours online. But, abstraction always means the loss of some detail.
- There is Misinterpretation Risk, because often the dependency might mistake your instructions. This is endemic in software, where it's nearly impossible to describe exactly what you want up-front.

14.9 Fit Risk

Sometimes, the bus will take you to lots of in-between places you *didn't* want to go. This is Fit Risk. There, we considered two problems:

²³https://en.wikipedia.org/wiki/Information_silo#Silo_mentality

- Risks you face when providing features for your clients.

Figure 14.6: Feature Fit Risk

- The feature (or now, dependency) doesn't provide all the functionality you need. This was Fit Risk. An example might be the supermarket not stocking everything you wanted.
- The feature / dependency provides far too much, and you have to accept more complexity than you need. This was Conceptual Integrity Risk. An example of this might be the supermarket being *too big*, and you spend a lot longer navigating it than you wanted to.

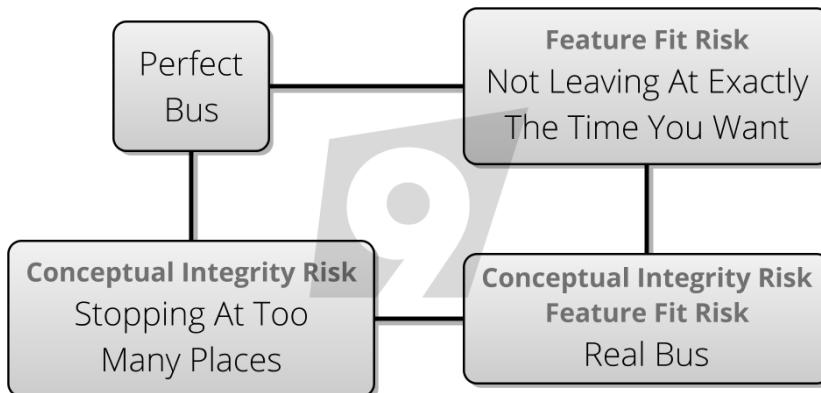

Figure 14.7: Feature Fit: A Two-Dimensional Problem (at least)

14.10 Dead-End Risk and Boundary Risk

When you choose something to depend on, you can't be certain that it's going to work out in your favour. Sometimes, the path from your starting point to your goal on the Risk Landscape, which we looked at before.

Boundary Risk if you've not had to follow a path to get to it.

We're also going to look at Boundary Risk in more detail later, but I want to introduce it here. Here are some examples:

- If I choose to program some software in Java, I will find it hard to integrate libraries from other languages. The dependencies available to Java software are different to those in Javascript, or C#. Having gone down a Java route, there are *higher risks* associated with choosing incompatible technologies. Yes, I can pick dependencies that use C# (still), but I am now facing greater complexity risk than if I'd just chosen to do everything in C# in the first place.
- If I choose one database over another, I am *limited to the features of that database*. This is not the same as a dead-end: I can probably build what I want to build, but the solution will be “bounded” by the dependency choices I make. One of the reasons we have standards like Java Database Connectivity (JDBC)²⁴ is to mitigate Dead End Risk²⁵ around databases, so that we can move to a different database later.
- If I choose to buy a bus ticket, I've made a decision not to travel by train, even though later on it might turn out that the train was a better option. Buying the bus ticket is Boundary Risk: I may be able to get a refund, but having chosen the dependency I've set down a path on the risk landscape.

14.11 Managing Dependency Risk

Arguably, managing Dependency Risk by organising the available dependencies into some kind of useful order.

There are *some* tools for managing dependency risk: Gantt Charts²⁶ for example, arrange work according to the capacity of the resources (i.e. dependencies) available, but also the *dependencies between the tasks*. If task **B** requires the outputs of task **A**, then clearly task **A** comes first and task **B** starts after it finishes. We'll look at this more in Process Risk²⁷.

We'll look in more detail at project management in the *practices* part, later. But now let's get into the specifics with Schedule Risk.

²⁴https://en.wikipedia.org/wiki/Java_Database_Connectivity

²⁵Complexity-Risk#dead-end-risk

²⁶https://en.wikipedia.org/wiki/Gantt_chart

²⁷Process-Risk

Schedule Risk

Schedule Risk is the term for risks you face because of *lack of time*.

You could also call this “Chronological Risk” or just “Time Risk” if you wanted to.

- The aspect of dependency risk related to time.

Figure 15.1: Schedule Risk

Schedule Risk is very pervasive, and really underlies *everything* we do. People *want* things, but they *want them at a certain time*. We need to eat and drink every day, for example. We might value having a great meal, but not if we have to wait three weeks for it.

And let's go completely philosophical for a second: Were you to attain immortality, you'd probably not feel the need to buy *anything*. You'd clearly have no *needs*, and anything you wanted, you could create yourself within your infinite time-budget. Rocks don't need money, after all.

Let's look at some specific kinds of Schedule Risk.

- Risk that a particular set of market conditions

Figure 15.2: Opportunity Risk

15.1 Opportunity Risk

Opportunity Risk¹ is really the concern that whatever we do, we have to do it *in time*. If we wait too long, we'll miss the Window Of Opportunity² for our product or service.

Any product idea is necessarily of it's time: the Goal In Mind, reflecting a view on reality at a specific *point in time*.

How long will that remain true for? This is your *opportunity*: it exists apart from any deadlines you set yourself, or funding options. It's purely, "how long will this idea be worth doing?"

With any luck, decisions around *funding* your project will be tied into this, but it's not always the case. It's very easy to undershoot or overshoot the market completely and miss the window of opportunity.

The iPad

For example, let's look at the iPad³, which was introduced in 2010 and was hugely successful.

This was not the first tablet computer. Apple had already tried to introduce the Newton⁴ in 1989, and Microsoft had released the Tablet PC⁵ in 1999. But somehow, they both missed the Window Of Opportunity⁶. Possibly, the window existed because Apple had changed changed the market with their release of the iPhone, which left people open to the idea of a tablet being "just a bigger iPhone".

¹Schedule-Risk#opportunity-risk

²https://en.wikipedia.org/wiki/Window_of_opportunity

³https://en.wikipedia.org/wiki/History_of_tablet_computers

⁴https://en.wikipedia.org/wiki/Apple_Newton

⁵https://en.wikipedia.org/wiki/Microsoft_Tablet_PC

⁶https://en.wikipedia.org/wiki/Window_of_opportunity

But maybe now, the iPad's window is closing? We have more *wearable computers* like the Apple Watch⁷, and voice-controlled devices like Alexa⁸ or Siri⁹. Peak iPad was in 2014, according to this graph¹⁰.

So, it seems Apple timed the iPad to hit the peak of the Window of Opportunity.

But, even if you time the Window Of Opportunity correctly, you might still have the rug pulled from under your feet due to a different kind of Schedule Risk, such as ...

15.2 Deadline Risk

- Where the use of a dependency has some kind of deadline, which can be missed.

Figure 15.3: Deadline Risk

Often when running a software project, you're given a team of people and told to get something delivered by a certain date. i.e. you have an artificially-imposed Deadline on delivery.

What happens if you miss the deadline? It could be:

- The funding on the project runs out, and it gets cancelled.
- You have to go back to a budgeting committee, and get more money.
- The team gets replaced, because of lack of faith.

.. or something else.

Deadlines can be set by an authority in order to *sharpen focus* and reduce Coordination Risk¹¹. This is how we arrive at tools like SMART Objectives¹² and KPI's (Key Performance Indicators)¹³. Time scales change the way we evaluate goals, and the solutions we choose.

⁹<https://en.wikipedia.org/wiki/Siri>

¹⁰<https://www.statista.com/statistics/269915/global-apple-ipad-sales-since-q3-2010/>

¹¹Coordination-Risk

¹²https://en.wikipedia.org/wiki/SMART_criteria

¹³https://en.wikipedia.org/wiki/Performance_indicator

In JFK's quote:

First, I believe that this nation should commit itself to achieving the goal, before this decade is out, of landing a man on the moon and returning him safely to the Earth.

The 9-year timespan came from an authority figure (the president) and helped a huge team of people coordinate their efforts and arrive at a solution that would work within a given time-frame.

Compare with this quote:

"I love deadlines. I love the whooshing noise they make as they go by." - Douglas Adams¹⁴

As a successful author, Douglas Adams *didn't really care* about the deadlines his publisher's gave him. The Deadline Risk was minimal for him, because the publisher wouldn't be able to give his project to someone else to complete.

Sometimes, deadlines are set in order to *coordinate work between teams*. The classic example being in a battle, to coordinate attacks. When our deadlines are for this purpose, we're heading towards Coordination Risk territory.

Student Syndrome

Student Syndrome¹⁵ is, according to Wikipedia:

Student syndrome refers to planned procrastination, when, for example, a student will only start to apply themselves to an assignment at the last possible moment before its deadline.

Arguably, there is good psychological, evolutionary and risk-based reasoning behind procrastination: the further in the future the Deadline Risk is, the more we discount it. If we're only ever mitigating our *biggest risks*, then deadlines in the future don't matter so much, do they? And, putting efforts into mitigating future risks that *might not arise* is wasted effort.

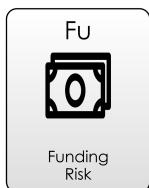

Or at least, that's the argument. If you're Discounting the Future To Zero then you'll be pulling all-nighters in order to deliver any assignment.

¹⁴https://en.wikipedia.org/wiki/Douglas_Adams

¹⁵https://en.wikipedia.org/wiki/Student_syndrome

So, the problem with Student Syndrome *later* than you would have with the original, pressing deadline . . . and you end up being late because of them. We'll look at mitigations for this in Part 3's chapter on Prioritisation.

15.3 Funding Risk

- A particular scarcity risk, due to lack of funding.

Figure 15.4: Funding Risk

On a lot of software projects, you are “handed down” deadlines from above, and told to deliver by a certain date or face the consequences. But sometimes you’re given a budget instead, which really just adds another layer of abstraction to the Schedule Risk: That is, do I have enough funds to cover the team for as long as I need them?

This grants you some leeway as now you have two variables to play with: the *size* of the team, and *how long* you can run it for. The larger the team, the shorter the time you can afford to pay for it.

In startup circles, this “amount of time you can afford it” is called the “Runway”¹⁶: you have to get the product to “take-off” before the runway ends. So you could term this component as “Runway Risk”.

Startups often spend a lot of time courting investors in order to get funding and mitigate this type of Schedule Risk, as usually the same people are trying to raise funds as build the project itself.

15.4 Staff Risk

If a startup has a “Runway”, then the chances are that the founders and staff do too, as this article explores¹⁷. It identifies the following risks:

¹⁶<https://en.wiktionary.org/wiki/runway>

¹⁷<https://www.entrepreneur.com/article/223135>

- The aspect of dependency risks related to employing people.

Figure 15.5: Staff Risk

- Company Cash: The **Runway** of the startup itself
- Founder Cash: The **Runway** for a founder, before they run out of money and can't afford their rent.
- Team Cash: The **Runway** for team members, who may not have the same appetite for risk as the founders do.

You need to consider how long your staff are going to be around, especially if you have Key Man Risk¹⁸ on some of them. People like to have new challenges, or move on to live in new places, or simply get bored. The longer your project goes on for, the more Staff Risk¹⁹ you will have to endure, and you can't rely on getting the best staff for failing projects²⁰.

In the chapter on Coordination-Risk.

15.5 Red-Queen Risk

- The general risk that the competitive environment we operate within changes over time.

Figure 15.6: Red Queen Risk

¹⁸https://en.wikipedia.org/wiki/Key_person_insurance#Key_person_definition

¹⁹Schedule-Risk#staff-risk

²⁰Agency-Risk

A more specific formulation of Schedule Risk, which is that whatever you build at the start of the project will go slowly more-and-more out of date as the project goes on.

This is named after the Red Queen quote from Alice in Wonderland:

“My dear, here we must run as fast as we can, just to stay in place. And if you wish to go anywhere you must run twice as fast as that.” - Lewis Carroll, *Alice in Wonderland*²¹

The problem with software projects is that tools and techniques change *really fast*. In 2011, 3DRealms released Duke Nukem Forever after 15 years in development²², to negative reviews:

... most of the criticism directed towards the game’s long loading times, clunky controls, offensive humor, and overall aging and dated design.

Now, they didn’t *deliberately* take 15 years to build this game (lots of things went wrong). But, the longer it took, the more their existing design and code-base were a liability rather than an asset.

Personally, I have suffered the pain on project teams where we’ve had to cope with legacy code and databases because the cost of changing them was too high. And any team who is stuck using Visual Basic 6.0²³ is here. It’s possible to ignore Red Queen Risk²⁴ for a time, but this is just another form of Technical Debt²⁵ which eventually comes due.

15.6 Schedule Risk and Feature Risk

In the chapter on Feature Risk, the idea that the value of your product is itself at risk from the morsés of the market, share prices being the obvious example of that effect. In Finance, we measure this using *money*, and we can put together probability models based on how much money you might make or lose.

With Schedule Risk, the underlying measure is *time*:

²¹<https://www.goodreads.com/quotes/458856-my-dear-here-we-must-run-as-fast-as-we>

²²https://en.wikipedia.org/wiki/Duke_Nukem_Forever

²³https://en.wikipedia.org/wiki/Visual_Basic

²⁴Schedule-Risk#red-queen-risk

²⁵Complexity-Risk

- “If I implement feature X, I’m picking up something like 5 days of Schedule Risk.”
- “If John goes travelling that’s going to hit us with lots of Schedule Risk while we train up Anne.”

... and so on. Clearly, in the same way as you don’t know exactly how much money you might lose or gain on the stock-exchange, you can’t put precise numbers on Schedule Risk either.

Schedule Risk.

Software Dependency Risk

In this chapter, we're going to look specifically at *Software* dependencies, although many of the concerns we'll raise here apply equally to all the other types of dependency we outlined in Dependency Risk.

16.1 Kolmogorov Complexity: Cheating

In the earlier chapter on Complexity Risk, and the idea that your codebase had some kind of minimal level of complexity based on the output it was trying to create. This is a neat idea, but in a way, we cheated. Let's look at how.

We were trying to figure out the shortest (Javascript) program to generate this output:

And we came up with this:

Which had **26** symbols in it.

Now, here's the cheat: The `repeat()` function was built into Javascript in 2015 in ECMAScript 6.0¹. If we'd had to program it ourselves, we might have

¹<http://www.ecma-international.org/ecma-262/6.0/>

added this:

```
function repeat(s,n) {          (10 symbols)
    var a=[];                  (7 symbols)
    while(a.length<n){        (9 symbols)
        a.push(s)              (6 symbols)
    }                          (1 symbol)
    return a.join('');         (10 symbols)
}                                (1 symbol)
```

... which would be an extra **44** symbols (in total **70**), and push us completely over the original string encoding of **53** symbols. So, *encoding language is important*.

Conversely, if ECMAScript 6.0 had introduced a function called abcdRepeater(n) we'd have been able to do this:

```
function out() {                (7 symbols)
    return abcdRepeater(10)      (6 symbols)
}                                (1 symbol)
```

.. and re-encode to **14** symbols. Now, clearly there are some problems with all this:

1. Clearly, *language matters*: the Kolmogorov complexity is dependent on the language, and the features the language has built in.
2. The exact Kolmogorov complexity is uncomputable anyway (it's the *theoretical* minimum program length). It's just a fairly abstract idea, so we shouldn't get too hung up on this. There is no function to be able to say, "what's the Kolmogorov complexity of string X"
3. What is this new library function we've created? Is abcdRepeater going to be part of *every* Javascript? If so, then we've shifted Codebase Risk
4. Are there equivalent functions for every single other string? If so, then compilation is no longer a tractable problem: is return abcdRepeater(10) correct code? Well, now we have a massive library of different XXXRepeater functions to compile against to see if it is... So, what we *lose* in Kolmogorov Complexity.
5. Language design, then, is about *ergonomics*. After you have passed the relatively low bar of providing Turing Completeness², the key is to provide *useful* features that enable problems to be solved, without

²https://en.wikipedia.org/wiki/Turing_completeness

over-burdening the user with features they *don't* need. And in fact, all software is about this.

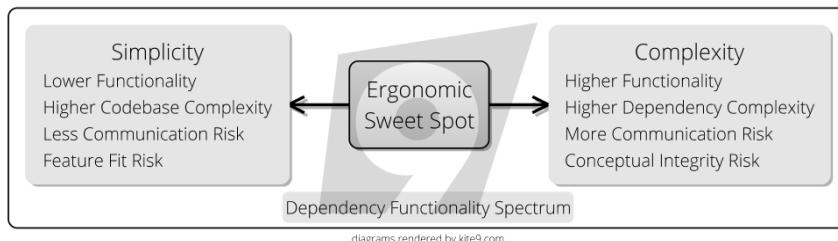

Figure 16.1: Software Dependency Ergonomics: finding the sweet spot between too many features and too few

16.2 Ergonomics Examined

Have a look at some physical tools, like a hammer, or spanner. To look at them, they are probably *simple* objects, obvious, strong and dependable. Their entire behaviour is encapsulated in their form. Now, if you have a drill or sander to hand, look at the design of this too. If it's well-designed, then from the outside it is simple, perhaps with only one or two controls. Inside, it is complex and contains a motor, perhaps a transformer, and is maybe made of a hundred different components.

But outside, the form is simple, and designed for humans to use. This is *ergonomics*³:

“Human factors and ergonomics (commonly referred to as Human Factors), is the application of psychological and physiological principles to the (engineering and) design of products, processes, and systems. The goal of human factors is to reduce human error, increase productivity, and enhance safety and comfort with a specific focus on the interaction between the human and the thing of interest.”

—Human Factors and Ergonomics, Wikipedia⁴

Interfaces

The interface of a tool is the part we touch and interact with. By striving for simplicity, the interface reduces Communication Risk.

³https://en.wikipedia.org/wiki/Human_factors_and_ergonomics

⁴https://en.wikipedia.org/wiki/Human_factors_and_ergonomics

The interface of a system expands when you ask it to do a wide variety of things. An easy-to-use drill does one thing well: it turns drill-bits at useful levels of torque for drilling holes and sinking screws. But if you wanted it to also operate as a lathe, a sander or a strimmer (all basically mechanical things going round) you would have to sacrifice the ergonomic simplicity for a more complex interface, probably including adapters, extensions, handles and so on.

So, we now have split complexity into two: - The inner complexity of the tool (how it works internally, it's own Kolmogorov Complexity). - The complexity of the instructions that we need to write to make the tool work (the interface Kolmogorov Complexity).

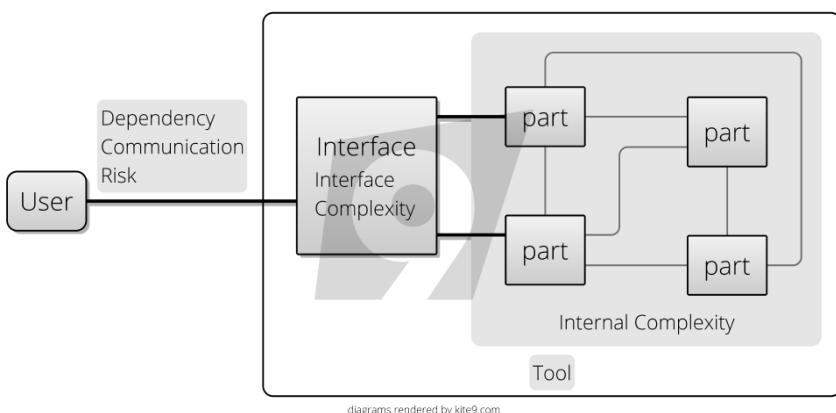

Figure 16.2: Types of Complexity For a Software Dependency

Software Tools

In the same way as with a hand-tool, the bulk of the complexity of a software tool is hidden behind its interface. But, the more complex the *purpose* of the tool, the more complex the interface will be.

Software is not constrained by *physical* ergonomics in the same way as a tool is. But ideally, it should have conceptual ergonomics: ideally, complexity is hidden away from the user behind the Application Programming Interface (API)⁵. This is the familiar concept of Abstraction⁶ we've already looked at.

That is, the tool should be as simple to use and understand as possible. This is the Principal Of Least Astonishment⁷:

⁵https://en.wikipedia.org/wiki/Application_programming_interface

⁶Glossary#abstraction

⁷https://en.wikipedia.org/wiki/Principle_of_least_astonishment

- **The abstractions should map easily to how the user expects the tool to work.** For example, I *expect* the trigger on a drill to start the drill turning.
- **The abstractions should leverage existing idioms and knowledge.** In a new car, I *expect* to know what the symbols on the dashboard mean, because I've driven other cars.
- **The abstractions provide me with only the functions I need.** Because everything else is confusing and gets in the way.

The way to win, then, is to allow a language to be extensible as-needed with features written by third parties. By supplying mechanisms for extension a language can provide insurances against the Boundary Risk of adopting it.

16.3 Types Of Software Dependencies

There are lots of ways you can depend on software. Here though, we're going to focus on just three main types: 1. **Code Your Own:** write some code ourselves to meet the dependency. 2. **Software Libraries:** importing code from the Internet, and using it in our project. Often, libraries are Open Source (this is what we'll consider here). 3. **Software as a Service:** calling a service on the Internet, (probably via `http`) This is often known as SaaS, or Software as a Service⁸.

All 3 approaches involve a different risk-profile. Let's look at each in turn, from the perspective of which risks get mitigated, and which risks are accentuated.

1. Code Your Own

Initially, writing our own code was the only game in town: when I started programming, you had a user guide, BASIC and that was pretty much it. Tool support was very thin-on-the-ground. Programs and libraries could be distributed as code snippets *in magazines* which could be transcribed and run, and added to your program. This spirit lives on somewhat in StackOverflow and JSFiddle, where you are expected to "adopt" others' code into your own project.

One of the hidden risks of embarking on a code-your-own approach is that the features you need are *not* apparent from the outset. What might appear to be a trivial implementation of some piece of functionality can often turn into its own industry as more and more hidden Feature Risk is uncovered.

⁸https://en.wikipedia.org/wiki/Software_as_a_service

For example, as we discussed in our earlier treatment of Dead-End Risk, building log-in screens *seemed like a good idea*. However, this gets out-of-hand fast when you need: - A password reset screen - To email the reset links to the user - An email verification screen - A lost account screen - Reminders to complete the sign up process - . . . and so on.

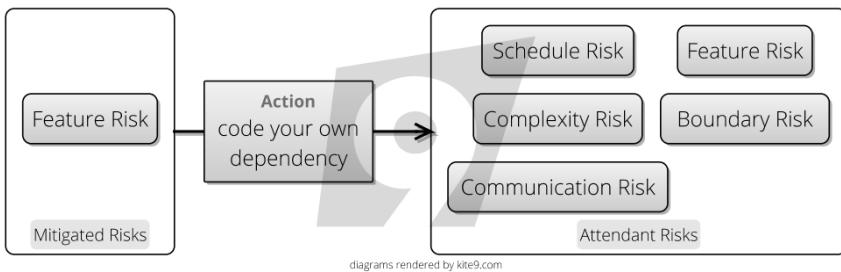

Figure 16.3: Code-Your-Own mitigates immediate feature risk, but at the expense of schedule risk, complexity risk and communication risk. There is also a hidden risk of features you don't yet know you need.

Unwritten Software

Sometimes, you will pick up a dependency on *unwritten software*. This commonly happens when work is divided amongst team members, or teams.

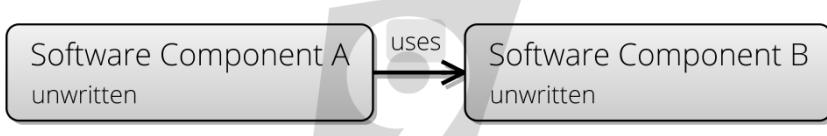

Figure 16.4: Sometimes, a module you're writing will depend on unwritten code

If a component **A** of our project *depends* on **B** for some kind of processing, you might not be able to complete **A** before writing **B**. This makes *scheduling* the project harder, and if component **A** is a risky part of the project, then the chances are you'll want to mitigate risk there first.

But it also hugely increases Communication Risk because now you're being asked to communicate with a dependency that doesn't really exist yet, *let alone* have any documentation.

There are a couple of ways to do this:

- **Standards:** If component **B** is a database, a queue, mail gateway or something else with a standard interface, then you're in luck. Write **A** to those standards, and find a cheap, simple implementation to test with. This gives you time to sort out exactly what implementation of **B** you're going for. This is not a great long-term solution, because obviously, you're not using the *real* dependency- you might get surprised when the behaviour of the real component is subtly different. But it can reduce Schedule Risk in the short-term.
- **Coding To Interfaces:** If standards aren't an option, but the surface area of **B** that **A** uses is quite small and obvious, you can write a small interface for it, and work behind that, using a Mock⁹ for **B** while you're waiting for finished component. Write the interface to cover only what **A needs**, rather than everything that **B does** in order to minimize the risk of Leaky Abstractions¹⁰.

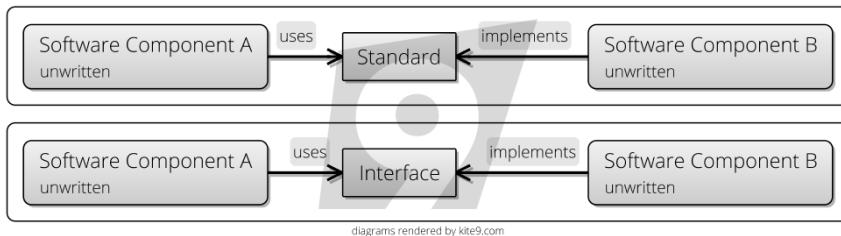

Figure 16.5: Coding to a standard on an interface breaks the dependency on unwritten software

Conway's Law

If the dependency is being written by another person, another team or in another country, communication risks pile up. When this happens, you will want to minimize *as much as possible* the interface complexity, since the more complex the interface, the worse the Communication Risk will be. The tendency then is to make the interfaces between teams or people *as simple as possible*, modularizing along these organisational boundaries.

In essence, this is Conway's Law¹¹:

organizations which design systems . . . are constrained to produce designs which are copies of the communication structures of these organizations.

2. Software Libraries

By choosing a particular software library, we are making a move on the Risk Landscape. But, in return we expect to pick up:

- Communication Risk: because we now have to learn how to communicate with this new dependency.
- Boundary Risk - because now are limited to using the functionality provided by this dependency. We have chosen it over alternatives and changing to something else would be more work and therefore costly.

But, it's quite possible that we could wind up in a worse place than we started out, by using a library that's out-of-date, riddled with bugs or badly supported. i.e. Full of new, hidden Feature Risk.

It's *really easy* to make bad decisions about which tools to use because the tools don't (generally) advertise their deficiencies. After all, they don't generally know how *you* will want to use them.

Software Libraries - Hidden Risks

Currently, choosing software dependencies looks like a "bounded rationality"-type process:

"Bounded rationality is the idea that when individuals make decisions, their rationality is limited by the tractability of the decision problem, the cognitive limitations of their minds, and the time available to make the decision."

—Bounded Rationality, *Wikipedia*¹²

Unfortunately, we know that most decisions *don't* really get made this way. We have things like Confirmation Bias¹³ (looking for evidence to support a decision you've already made) and Cognitive Inertia¹⁴ (ignoring evidence that would require you to change your mind) to contend with.

But, leaving that aside, let's try to build a model of what this decision making process *should* involve. Luckily, other authors have already considered the problem of choosing good software libraries, so let's start there.

In the table below, I am summarizing three different sources (linked at the end of the chapter), which give descriptions of which factors to look for when choosing open-source libraries.

Figure 16.6: Software Dependencies

- Feature Risk is a big concern. How can you be sure that the project will do what you want it to do ahead of schedule? Will it contain bugs or missing features? By looking at factors like *release frequency* and *size of the community* you get a good feel for this which is difficult to fake.
- Boundary Risk is also very important. You are going to have to *live* with your choices for the duration of the project, so it's worth spending the effort to either ensure that you're not going to regret the decision, or that you can change direction later.
- Third is Communication Risk is also a good reason to pick *tools you are already familiar with*.

Complexity Risk?

One thing that none of the sources consider (at least from the outset) is the Complexity Risk of using a solution: - Does it drag in lots of extra dependencies that seem unnecessary for the job in hand? If so, you could end up in Dependency Hell¹⁵, with multiple, conflicting versions of libraries in the project. - Do you already have a dependency providing this functionality? So many times, I've worked on projects that import a *new* dependency when some existing (perhaps transitive) dependency has *already brought in the functionality*. For example, there are plenty of libraries for JSON¹⁶ marshalling, but if I'm also using a web framework the chances are it already has a dependency on one already. - Does it contain lots of functionality that isn't relevant to the task you want it to accomplish? e.g. Using Java when a shell script would do (on a non-Java project)

To give an extreme example of this, I once worked on an application which used Hazelcast¹⁷ to cache log-in session tokens for a 3rd party datasource. But, the app is only used once every month, and session IDs can be obtained in milliseconds. So... why cache them? Although Hazelcast is an excellent choice for in-memory caching across multiple JVMs, it is a complex piece of software (after all, it does lots of stuff). By doing this, you have introduced extra dependency risk, cache invalidation risks, networking risks, synchronisation risks and so on, for actually no benefit at all... Unless, it's about CV Building¹⁸.

Sometimes, the amount of complexity *goes up* when you use a dependency for *good reason*. For example, in Java, you can use Java Database Connectivity

(JDBC)¹⁹ to interface with various types of database. Spring Framework²⁰ (a popular Java library) provides a thing called a `JDBCTemplate`. This actually makes your code *more* complex, and can prove very difficult to debug. However, it prevents some security issues, handles resource disposal and makes database access more efficient. None of those are essential to interfacing with the database, but not using them is Technical Debt²¹ that can bite you later on.

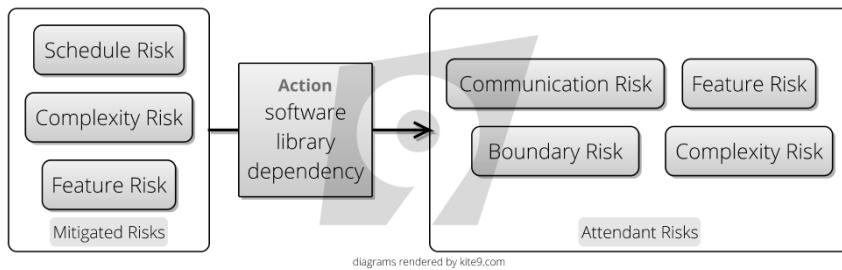

Figure 16.7: Software Libraries Risk Tradeoff

3. Software as a Service

Businesses opt for Software as a Service (SaaS) because:

- It vastly reduces the Complexity Risk they face in their organisations. e.g. managing the software or making changes to it.
- Payment is usually based on *usage*, mitigating Schedule Risk. e.g. Instead of having to pay for in-house software administrators, they can leave this function to the experts.
- Potentially, you outsource the Operational Risk to a third party. e.g. ensuring availability, making sure data is secure and so on.

SaaS is now a very convenient way to provide *commercial* software. Popular examples of SaaS might be SalesForce²², or GMail²³. Both of which follow the commonly-used Freemium²⁴ model, where the basic service is provided free, but upgrading to a paid account gives extra benefits.

By providing the software on their own servers, the commercial organisation has a defence against *piracy*, as well as being able to control the Complexity Risk.

Let's again recap the risks raised in some of the available literature:

Figure 16.8: Software As A Service Dependencies

Some take-aways:

- Clearly, Operational Risk is now a big concern. By depending on a third-party organisation you are tying yourself to its success or failure in a much bigger way than just by using a piece of open-source software. What happens to data security, both in the data centre and over the internet?
- With Feature Risk you now have to contend with the fact that the software will be upgraded *outside your control*, and you may have limited control over which features get added or changed.
- Boundary Risk.

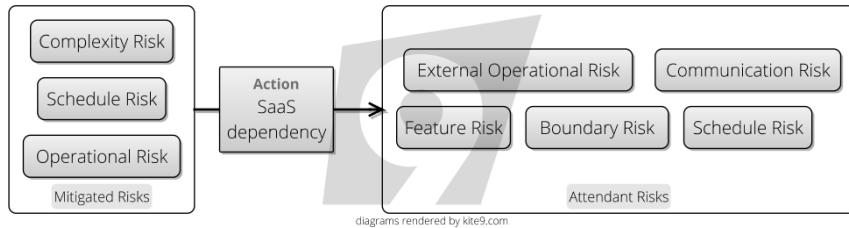

Figure 16.9: Risk Tradeoff From Using _Software as a Service (SaaS)

16.4 A Matrix of Options

We've looked at just 3 different ways of providing a software dependency: SaaS, Libraries and code-your-own.

But these are not the only ways to do it, and there's clearly no one *right* way. Although here we have looked just at "Commercial SaaS" and "Free Open Source", in reality, these are just points in a two-dimensional space involving *Pricing* and *Hosting*.

Let's expand this view slightly and look at where different pieces of software sit on these axes:

- Where there is value in the Network Effect²⁵, it's often a sign that the software will be free, or open source: programming languages and Linux are the obvious examples of this. Bugs are easier to find when there are lots of eyes looking, and learning the skill to use the software has less Boundary Risk²⁶ if you know you'll be able to use it at any point in the future.
- At the other end of the spectrum, clients will happily pay for software if it clearly **reduces complexity**. Take Amazon Web Services (AWS)²⁷. The essential trade here is that you substitute the complexity of hosting and maintaining various pieces of software, in exchange for monthly payments (Funding Risk²⁸ for you). Since the AWS *interfaces* are specific to Amazon, there is significant Boundary Risk²⁹ in choosing this option.
- In the middle there are lots of **substitute options** and therefore high competition. Because of this, prices are pushed towards zero, and therefore often advertising is used to monetarize the product. Angry

Managing Risks

So far, we've considered only how the different approaches to Software Dependencies or other.

But with Software Dependencies we can construct dependency networks to give us all kinds of features and mitigate all kinds of risk. That is, *the features we are looking for are to mitigate some kind of risk.*

For example, I might start using WhatsApp³³ for example, because I want to be able to send my friends photos and text messages. However, it's likely that those same features are going to allow us to mitigate Communication Risk³⁴ and Coordination Risk³⁵ when we're next trying to meet up.

Let's look at some:

Risk	Examples of Software Mitigating That Risk
Coordination Risk	Calendar tools, Bug Tracking, Distributed Databases
Map-And-Territory-Risk	The Internet, generally. Excel, Google, "Big Data", Reporting tools
Schedule-Risk	Planning Software, Project Management Software
Communication-Risk	Email, Chat tools, CRM tools like SalesForce, Forums, Twitter, Protocols
Process-Risk	Reporting tools, online forms, process tracking tools
Agency-Risk	Auditing tools, transaction logs, Timesheet software, HR Software
Operational-Risk	Support tools like ZenDesk, Grafana, InfluxDB, Geneos
Feature-Risk	Every piece of software you use!

16.5 Back To Ergonomics

What's clear from this analysis is that software dependencies don't *conquer* any risk - the moves they make on the Risk Landscape are *subtle*. Whether or not you end up in a more favourable position risk-wise is going to depend heavily on the quality of the execution and the skill of the implementor.

In particular, *choosing* dependencies can be extremely difficult. As we discussed above, the usefulness of any tool depends on its fit for purpose, it's *ergonomics within a given context*. It's all too easy to pick a good tool for the wrong job:

“I suppose it is tempting, if the only tool you have is a hammer, to treat everything as if it were a nail.”

—Abra-

ham Maslow, *Toward a Psychology of Being*³⁶ <!-- tweet-end -->

With software dependencies, we often have to live with the decisions we make for a long time. In my experience, given the Boundary Risks associated with getting this wrong, not enough time is spent really thinking about this in advance.

Let's take a closer look at this problem in the next chapter, Boundary Risk.

Process Risk

Process Risk, as we will see, is the risk you take on whenever you embark on completing a *process*.

“Process: A process is a set of activities that interact to achieve a result.”

—Process, *Wikipedia*¹

In the software development world (and the business world generally) processes commonly involve *forms*: If you’re filling out a form (whether on paper or on a computer) then you’re involved in a process of some sort, whether an “Account Registration” process, “Loan Application” process or “Consumer Satisfaction Survey” process. But sometimes, they involve events occurring: a build process² might start after you commit some code, for example.

17.1 The Purpose Of Process

Process exists to mitigate other kinds of risk, and for this reason, we’ll be looking at them again in Part 3: Practices, where we’ll look at how you can design processes to mitigate risks on your own project.

Until we get there, let’s look at some examples of how process can mitigate other risks:

- Coordination Risk³: You can often use process to help people coordinate. For example, a Production Line⁴ is a process where work being

¹<https://en.wikipedia.org/wiki/Process>

²https://en.wikipedia.org/wiki/Software_build

³Coordination-Risk

⁴https://en.wikipedia.org/wiki/Production_line

done by one person is pushed to the next person when it's done. A meeting booking process ensures that people will all attend a meeting together at the same place and time, and that a room is available for it.

- Dependency Risk onto the person asking for the loan, by making it part of the process and not accepting the application until this has been provided.
- Complexity Risk. mcdonalds. tbd
- Operational Risk itself.

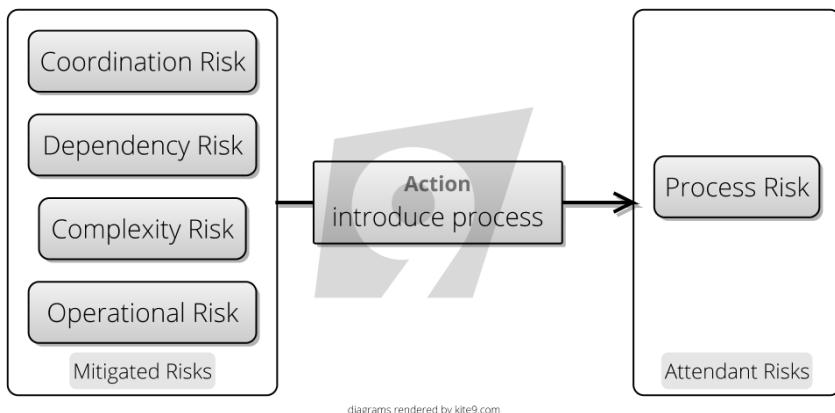

Figure 17.1: Introducing process can mitigate many risks for a team, but there are attendant process risks created.

These are all examples of Risk Mitigation. Let's see how this comes about.

17.2 Evolution Of Business Process

Before we get to examining what constitutes Process Risks⁵, let's consider how processes *form*. Specifically, we're going to look at Business Process⁶:

“Business Process or Business Method is a collection of related, structured activities or tasks that in a specific sequence produces a service or product (serves a particular business goal) for a particular customer or customers.”

—Business Process, Wikipedia⁷

⁵Process-Risk

⁶https://en.wikipedia.org/wiki/Business_process

⁷https://en.wikipedia.org/wiki/Business_process

Business Processes often arise in response to an unmet need within an organisation. And, as we said above, they are usually there to mitigate other risks. Let's look at an example lifecycle of how that can happen.

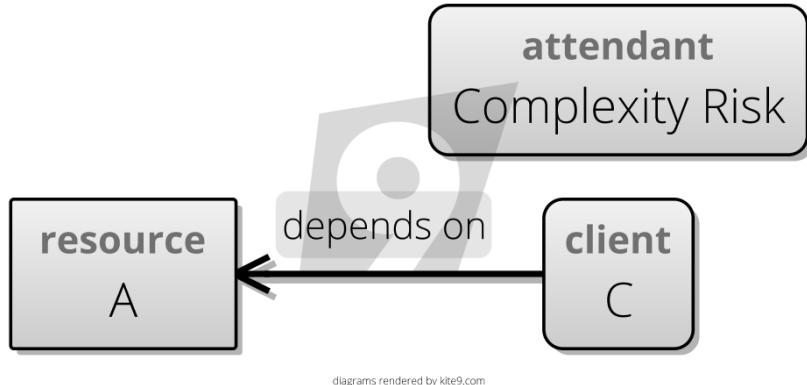

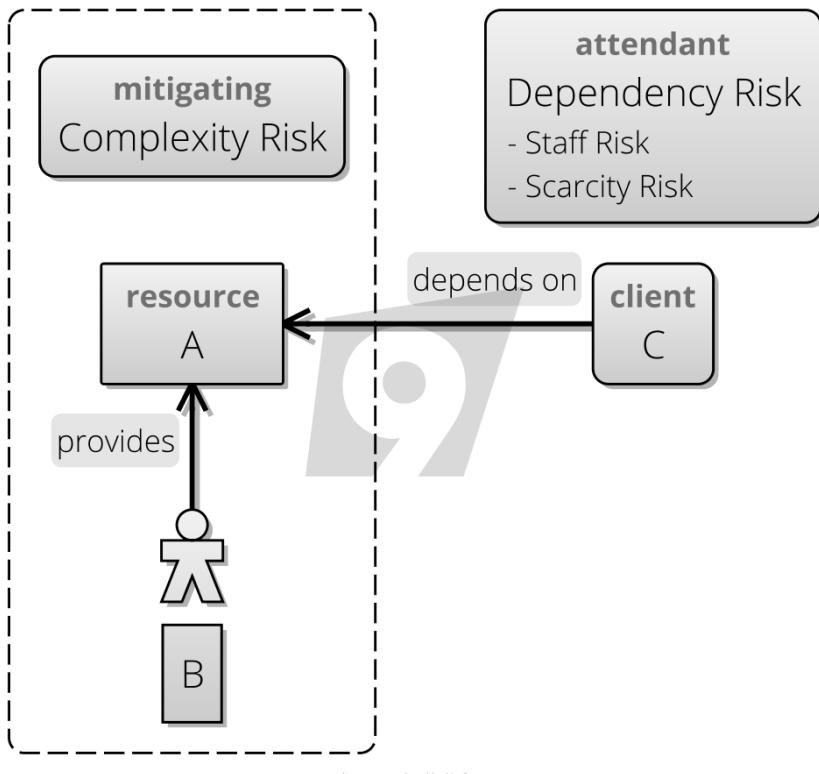

Figure 17.2: Step 0: Clients C need A to do their jobs

0. Let's say, there exists a group of people inside a company C, which need a certain something A in order to get their jobs done. It might be a producing a resource, or dealing with some source of complexity, or whatever.
1. Person B in a company starts producing A *as a service to others*. This is really useful! It makes the the lives of clients in C much easier as they have an easier path to A than before. B gets busy keeping C happy. No one cares. But then, B goes on holiday. A doesn't get done, and people now care: the Dependency Risk is suddenly apparent.
2. Either, B co-opts other people to help, gets given a team (T), or someone else forms a team T containing B to get the job done "properly".
 - T is responsible for doing A, but it needs to supply the company with A reliably and responsibly, otherwise there will be trouble, so they try and please all of their clients as far as possible.
 - This is a good deal for their clients within C, but because there is a lot of variation in what the clients ask for, T end up absorbing a lot of Complexity Risk and are overworked.

diagrams rendered by kite9.com

Figure 17.3: Step 1: Person B doing A for company C

- This is attendant Schedule Risk impacts their ability to reliably deliver A.
3. T organises bureaucratically, so that there is a controlled process (P) by which A can be accessed. Like a cell, they have arranged a protective barrier around themselves, the strength of which depends on the power conferred to them by control of A.
- P probably involves filling in a form (or following some other Protocol).
 - T can now deal with requests on a first-come-first-served basis and deal with them all in the same way: Complexity Risks are now the problem of the form-filler in C.
 - T has mitigated Schedule Risk they are willing to take on.
 - C now has Process Risk: will their requirements for A be met by T? They have to submit to the process to find out...

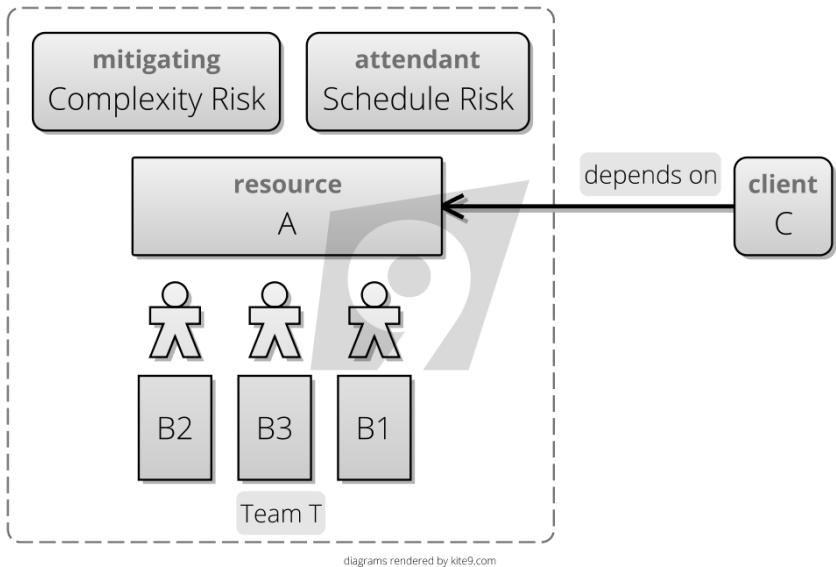

Figure 17.4: Step 2: Team T is created to do A for Company C

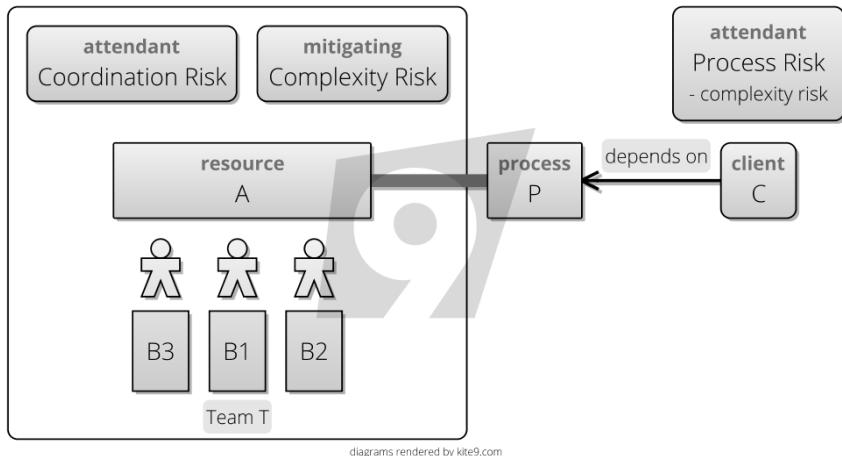

Figure 17.5: Team T protects itself from complexity with a process, P

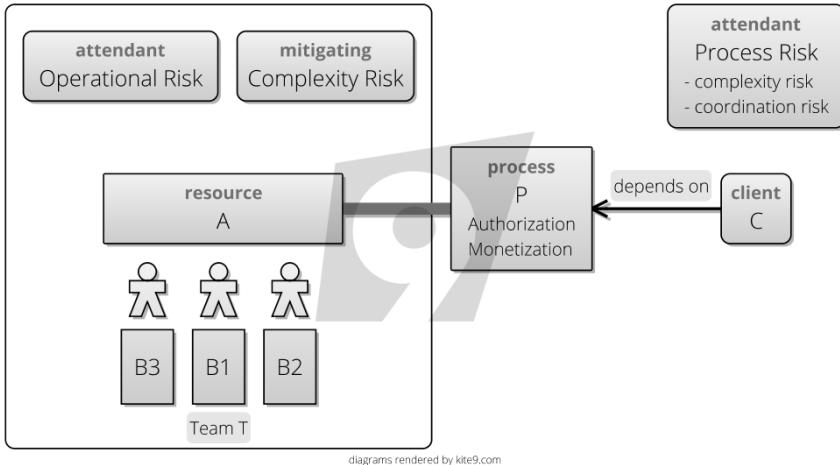

Figure 17.6: Team T protects itself from Coordination issues with signoffs or other barriers

4. But it's hard to make sure the right clients get access to A at the right times, and it's necessary to synchronize access across company C. (A Coordination Risk)
 - T reacts and sets up sign-off, authorization or monetary barriers around A, moving the Coordination Risk issue out of their team.
 - But, for C, this *again* increases the Process Risk involved in using A.
5. But, there are abuses of A: people either misuse it, or use it too much. (These are Operational Risks.)
 - T reacts by *increasing* the amount of process to use A, mitigating Operational Risk within their team, but...
 - This corresponds to greater Process Risk for clients in company C.
6. Person D, who has experience working with team T acts as a middleman for customers requiring some variant of A for a subset of C. They are able to help navigate the bureaucratic process (handle with Process Risk). The cycle potentially starts again: will D end up becoming a new team, with a new process?

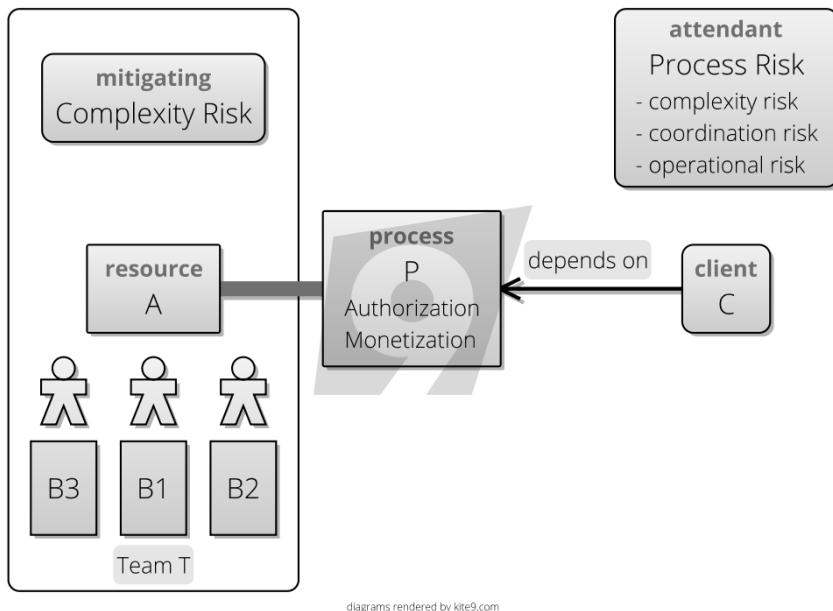

Figure 17.7: Team T increases bureaucratic load, and pushes Process Risk onto C

In this example, you can see how the organisation evolves to mitigate risk around the use (and misuse) of A: First, Complexity Risk was created to mitigate everything else. This is an example of *Process following Strategy*:

In this conception, you can see how the structure of an organisation (the teams and processes within it, the hierarchy of control) will 'evolve' from the resources of the organisation and the strategy it pursues. Processes evolve to meet the needs of the organisation." - Mintzberg, *Strategy Safari*⁸

17.3 An Example - Release Process

For many years I have worked in the Finance Industry, and it's given me time to observe how, across an entire industry, process can evolve, both in response to regulatory pressure but also because of organisational maturity, and mitigating risks:

⁸<http://www.mintzberg.org/books/strategy-safari>

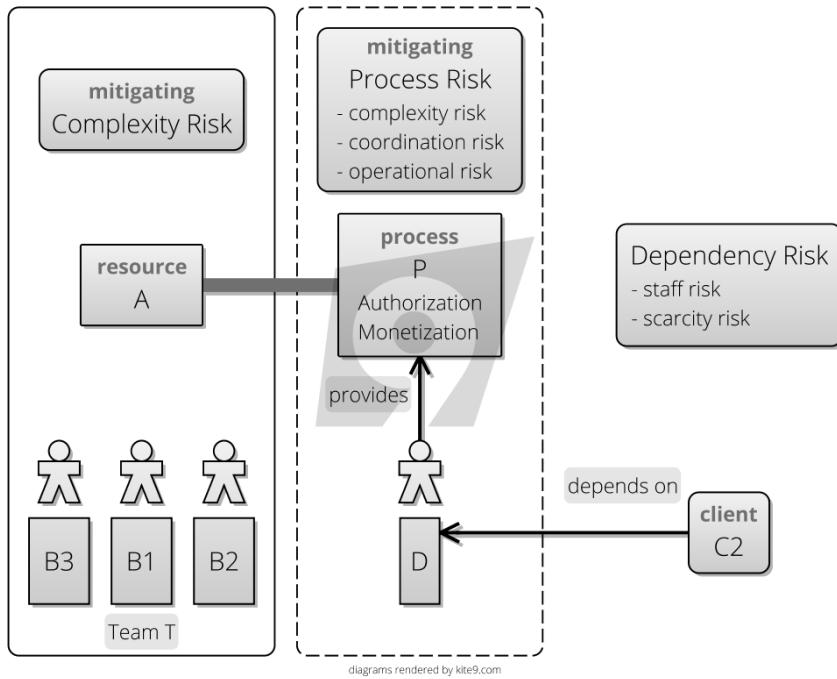

Figure 17.8: Person D acts as a middleman for customers needing some variant of A

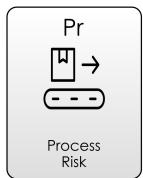

1. Initially, I could release software by logging onto the production accounts with a password that everyone knew, and deploy software or change data in the database.
2. The first issue with this is bad actors: How could you know that the numbers weren't being altered in the databases? Production auditing came in so that at least you could tell *who was changing what*, in order to point the blame later.
3. But, there was still plenty of scope for deliberate or accidental damage. I personally managed to wipe production data on one occasion by mistaking it for a development environment. Eventually, passwords were taken out of the hands of developers and you needed approval to "break glass" to get onto production.
4. Change Requests were introduced. This is another approval process which asks you to describe what you want to change in production, and why you want to change it. In most places, this was quite an onerous process, so the unintended consequence was that release cadence was reduced.
5. The change request software is generally awful, making the job of

raising change requests tedious and time-consuming. Therefore, developers would *automate* the processes for release, sometimes including the process to write the change request. This allowed them to improve release cadence, at the expense of owning more code.

6. Auditors didn't like the fact that this automation existed, because effectively, that meant that developers could get access to production with the press of a button, effectively taking you back to step 1. So auditing of Change Requests had to happen.

... and so on.

17.4 Process Risks

- Risks due to the fact that when dealing with a dependency, we have to follow a particular protocol of communication, which may not work out the way we want.

Figure 17.9: Process Risk

Process Risk, then, is a type of Dependency Risk manifests itself in fairly predictable ways:

- Reliability Risk the process is covering.
- Invisibility Risk for visibility: it's often not possible to see how far along a process is to completion. Sometimes, you can do this to an extent. For example, when I send a package for delivery, I can see roughly how far it's got on the tracking website. But, this is still less-than-complete information, and is a representation of reality.
- Fit Risk: You have to be careful to match the process to the outcome you want. Sometimes, it's easy to waste time on the wrong process.
- Dead-End Risk: Even if you have the right process, initiating a process has no guarantee that your efforts won't be wasted and you'll be back where you started from. The chances of this happening increase as you get further from the standard use-case for the process, and the sunk cost increases with the length of time the process takes to report back.
- Agency Risk: Due to Parkinson's Law, see below.

- Operational Risk, which we'll address further in its own chapter.
- Credit Risk: Where you pay for something to be done, but then end up without the outcome you want. Let's look at that in more detail.

Processes And Invisibility Risk

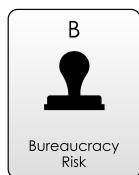

Processes tend to work well for the common cases, because *practice makes perfect*. but they are really tested when unusual situations occur. Expanding processes to deal with edge-cases incurs Complexity Risk, so often it's better to try and have clear boundaries of what is "in" and "out" of the process' domain.

Sometimes, processes are *not* used commonly. How can we rely on them anyway? Usually, the answer is to build in extra feedback loops anyway:

- Testing that backups work, even when no backup is needed.
- Running through a disaster recovery scenario at the weekend.
- Increasing the release cadence, so that we practice the release process more.

The feedback loops allow us to perform Retrospectives and Reviews to improve our processes.

Bureaucracy Risk

- Risk that a particular dependency devolves into a self-serving bureaucracy due to some kind of agency issue.

Figure 17.10: Bureaucracy Risk

Where we've talked about process evolution above, the actors involved have been acting in good faith: they are working to mitigate risk in the organisation. The Process Risk.

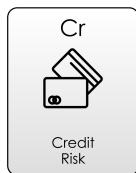

But Parkinson's Law⁹ takes this one step further: the human actors shaping the organisation will abuse their positions of power in order to further their own careers (this is Agency Risk¹⁰, which we will come to in a future chapter):

"Parkinson's law is the adage that "work expands so as to fill the time available for its completion". It is sometimes applied to the growth of bureaucracy in an organization... He explains this growth by two forces: (1) 'An official wants to multiply subordinates, not rivals' and (2) 'Officials make work for each other.'"

—Parkinson's Law, Wikipedia¹¹

This implies that there is a tendency for organisations to end up with *needless levels of Bureaucratic Risk*.

Credit Risk

- A specific version of reliability risk where the risk is due to money owed by one or other party.

Figure 17.11: Credit Risk

Where the process you depend on is being run by a third-party organisation, (or that party depends on you) you are looking at Credit Risk:

"A credit risk is the risk of default on a debt that may arise from a borrower failing to make required payments... For example... A business or consumer does not pay a trade invoice when due [or] A business does not pay an employee's earned wages when due"

—Credit Risk, Wikipedia¹²

¹²https://en.wikipedia.org/wiki/Credit_risk

Money is *changing hands* between you and the supplier of the process, and often, the money doesn't transfer *at the same time* as the process is performed. Let's look at an example: Instead of hosting my website on a server in my office, I could choose to host my software project with an online provider. I am trading Complexity Risk, because now, I have to care that the supplier is solvent.

There's a couple of ways this could go wrong: They may *take my payment*, but then turn off my account. Or, they could go bankrupt, and leave me with the costs of moving to another provider (this is also Dead-End Risk).

Mechanisms like insurance¹³, contracts¹⁴ and guarantees¹⁵ help mitigate this risk at the cost of complexity and expense.

Sign-Offs

Often, Processes will include sign-off steps. The Sign-Off is an interesting mechanism: - By signing off on something for the business, people are usually in some part staking their reputation on something being right. - Therefore, you would expect that sign-off involves a lot of Agency Risk: people don't want to expose themselves in career-limiting ways. - Therefore, the bigger the risk they are being asked to swallow, the more cumbersome and protracted the sign off process.

Often, Sign Offs of all the effort gone into getting the sign off if they don't.

This is a nasty situation, but there are a couple of ways to de-risk this: - break Sign Offs down into bite-size chunks of risk that are acceptable to those doing the sign-off. - Agree far-in-advance the sign-off criteria. As discussed in Risk Theory, people have a habit of heavily discounting future risk, and it's much easier to get agreement on the *criteria* than it is to get the sign-off.

Boundary Risk

- Risks due to the choices we make around dependencies, and the limitations they place on our ability to change.

Figure 18.1: Boundary Risk

In the previous few chapters on Dependency Risk several times, but now it's time to tackle it head-on and discuss this important type of risk.

In terms of the Risk Landscape, and introduces a maze-like component to it. It also means that we have to make *decisions* about which way to go, knowing that our future paths are constrained by the decisions we make.

- The risk that a particular approach to a change will fail. Caused by the fact that at some level, our internal models are not a complete reflection of reality.

Figure 18.2: Dead-End Risk

And, as we discussed in Complexity Risk, and we've done work that we need to throw away. In this case, we'll have to head back and make a different decision.

18.1 Emergence Through Choice

Boundary Risk. Because of that, it's going to take a bit of time to pick it apart and understand it, so we're going to build up to this in stages.

Let's start with an obvious example: Musical Instruments. Let's say you want to learn to play some music. There are a *multitude* of options available to you, and you might choose an *uncommon* instrument like a Balalaika¹ or a Theremin², or you might choose a *common* one like a piano or guitar. In any case, once you start learning this instrument, you have picked up the three risks above:

- Dependency Risk on it in order to play music, so get to the music shop and buy one.
- Communication Risk in order to be able to do that.
- Complexity Risk, with all the attendant complexity of looking after that instrument, tuning it, and so on.

Those risks are true for *any* instrument you choose. However, if you choose the *uncommon* instrument like the Balalaika³, you have *worse* Boundary Risk⁴, because the *ecosystem* for the balalaika is smaller. It might be hard to find a tutor, or a band needing a balalaika. You're unlikely to find one in a friend's house (compared to the piano, say).

Even choosing the Piano has Boundary Risk and changing to a different path is *expensive*.

Also, it stands to reason that making *any* choice is better than making *no* choice, because you can't try and learn *all* the instruments. Doing that, you'd make no meaningful progress on any of them.

18.2 Boundary Risk For Software Dependencies

Let's look at a software example now.

¹<https://en.wikipedia.org/wiki/Balalaika>

²<https://en.wikipedia.org/wiki/Theremin>

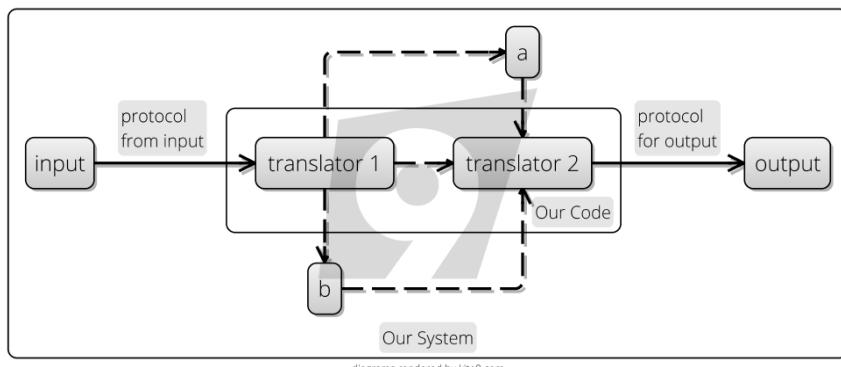

³<https://en.wikipedia.org/wiki/Balalaika>

⁴Boundary-Risk

As discussed in Software Dependency Risk of that interface. If you want to work with it, you have to use its protocol, it won't come to you.

Let's take a look at a hypothetical system structure, in the accompanying diagram. In this design, we have are transforming data from the input to the output. But how should we do it?

- We could go via a, using the Protocols of a, and having a dependency on a.
- We could go via b, using the Protocols of b, and having a dependency on b.
- We could choose the middle route, and avoid the dependency, but potentially pick up lots more Complexity Risk.

*Figure 18.3: Our System receives data from the **input**, translates it and sends it to the **output**. But which dependency should we use for the translation, if any?*

This is a basic **Translation** job from input to output. Since we are talking about **Translation**, we are clearly talking about Communication Risk again: our task in **Integrating** all of these components is *to get them to talk to each other*.

From a Cyclomatic Complexity, because we don't know that we'll be able to make them *talk to each other* properly:

- Maybe a outputs dates in a strange calendar format that we won't understand.
- Maybe b works on some streaming API basis, that is incompatible with the input protocol.
- Maybe a runs on Windows, whereas our code runs on Linux.

... and so on.

18.3 Boundary Risk Pinned Down

Wherever we integrate dependencies with complex Protocols. It is:

- The *sunk cost* of the Learning Curve we've overcome to integrate the dependency, when it fails to live up to expectations.
- The likelihood of, and costs of changing in the future.
- The rarity of alternatives (or, conversely, the risk of Lock In).

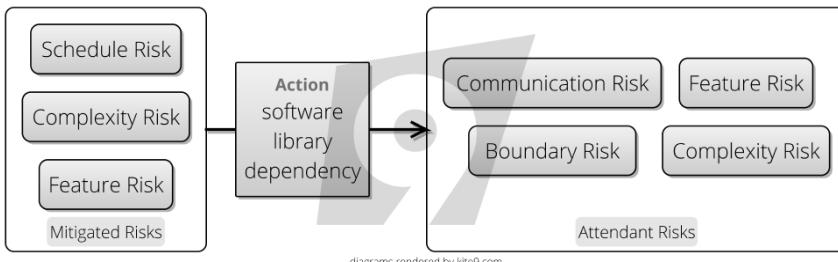

Figure 18.4: The tradeoff for using a library

As we saw in Software Dependency Risk is a big factor in choosing libraries and services. However, it can apply to any kind of dependency:

- If you're depending on a Process or Organisation, they might change their products or quality, making the effort you put into the relationship worthless.
- If you're depending on Staff, they might leave, meaning your efforts on training them don't pay back as well as you hoped.
- If you're depending on an Event occurring at a particular time, you might have a lot of work to reorganise your life if it changes time or place.

18.4 Avoiding Boundary Risk Now...

Because of Boundary Risk, we can avoid accreting it by choose the *simplest* and *fewest* dependencies for any job. Let's look at some examples:

- `mkdirp` is an npm⁵ module defining a single function. This function takes a single string parameter and recursively creating directories. Because the protocol⁶ is so simple, there is almost no Boundary Risk⁷.
- Using a database with a JDBC⁸ driver comes with *some* Boundary Risk⁹: but the boundary is specified by a standard. Although the standard doesn't cover every aspect of the behaviour of the database, it does minimize risk, because if you are familiar with one JDBC driver, you'll be familiar with them all, and swapping one for another is relatively easy.
- Using a framework like Spring¹⁰, Redux¹¹ or Angular¹² comes with higher Boundary Risk¹³: you are expected to yield to the framework's way of behaving throughout your application. You cannot separate the concern easily, and swapping out the framework for another is likely to leave you with a whole new set of assumptions and interfaces to deal with.

18.5 ... And In The Future

Unless your project *ends*, you can never be completely sure that Boundary Risk *isn't* going to stop you making a move you want. For example:

- `mkdirp` might not work on a new device's Operating System, forcing you to swap it out.
- You might discover that the database you chose satisfied all the features you needed at the start of the project, but came up short when the requirements changed later on.
- The front-end framework you chose might go out-of-fashion, and it might be hard to find developers interested in working on the project because of it.

This third point is perhaps the most interesting aspect of Boundary Risk.

18.6 Plugins, Ecosystems and Evolution

On the face of it, WordPress¹⁴ and Drupal¹⁵ *should* be very similar:

- They are both Content Management Systems¹⁶
- They both use a LAMP (Linux, Apache, MySQL, PHP) Stack¹⁷
- They were both started around the same time (2001 for Drupal, 2003 for WordPress)
- They are both Open-Source, and have a wide variety of Plugins¹⁸. That is, ways for other programmers to extend the functionality in new directions.

In practice, they are very different. This could be put down to different *design goals*: it seems that WordPress was focused much more on usability, and an easy learning curve, whereas Drupal supported plugins for building things with complex data formats. It could also be down to the *design decisions*: although they both support Plugins, they do it in very different ways.

(Side note: I wasn't short of go-to examples for this. I could have picked on Team City¹⁹ and Jenkins²⁰ here (Continuous Integration²¹ tools), or Maven²² and Gradle²³ (build tools). All of these support plugins²⁴, and the *choice* of plugins is dependent on which I've chosen, despite the fact that the platforms are solving pretty much the same problems.)

Ecosystems and Systems

The quality, and choice of plugins for a given platform, along with factors such as community and online documentation is often called its ecosystem²⁵:

“as a set of businesses functioning as a unit and interacting with a shared market for software and services, together with relationships among them”

—Software Ecosystem, Wikipedia²⁶

¹⁴<https://en.wikipedia.org/wiki/WordPress>

¹⁵<https://en.wikipedia.org/wiki/Drupal>

¹⁶https://en.wikipedia.org/wiki/Content_management_system

¹⁷[https://en.wikipedia.org/wiki/LAMP_\(software_bundle\)](https://en.wikipedia.org/wiki/LAMP_(software_bundle))

¹⁸[https://en.wikipedia.org/wiki/Plug-in_\(computing\)](https://en.wikipedia.org/wiki/Plug-in_(computing))

¹⁹<https://en.wikipedia.org/wiki/TeamCity>

²⁰[https://en.wikipedia.org/wiki/Jenkins_\(software\)](https://en.wikipedia.org/wiki/Jenkins_(software))

²³<https://en.wikipedia.org/wiki/Gradle>

²⁵https://en.wikipedia.org/wiki/Software_ecosystem

²⁶https://en.wikipedia.org/wiki/Software_ecosystem

You can think of the ecosystem as being like the footprint of a town or a city, consisting of the buildings, transport network and the people that live there. Within the city, and because of the transport network and the amenities available, it's easy to make rapid, useful moves on the Risk Landscape in a common way.

tbd: talk about complexity within the boundary. (increased convenience?)

Ecosystem size is one key determinant of Boundary Risk are unlikely to collide with it. The boundary *got large* because other developers before you hit the boundary and did the work building the software equivalents of bridges and roads and pushing it back so that the boundary didn't get in their way.

In a small ecosystem, you are much more likely to come into contact with the edges of the boundary. *You* will have to be the developer that pushes back the frontier and builds the roads for the others. This is hard work.

Evolution

In the real world, there is a tendency for *big cities to get bigger*. The more people that live there, the more services they provide, and therefore, the more immigrants they attract. And, it's the same in the software world. In both cases, this is due to the Network Effect²⁷:

"A network effect (also called network externality or demand-side economies of scale) is the positive effect described in economics and business that an additional user of a good or service has on the value of that product to others. When a network effect is present, the value of a product or service increases according to the number of others using it."

—Network Effect, *Wikipedia*²⁸

You can see the same effect in the adoption rates of WordPress and Drupal, shown in the chart below. Note: this is over *all sites on the internet*, so Drupal accounts for hundreds of thousands of sites. In 2018, WordPress is approximately 32% of all websites. For Drupal it's 2%.

Did WordPress gain this march because it was better than Drupal? That's arguable. That it's this way round could be *entirely accidental*, and a result of Network Effect.

²⁷https://en.wikipedia.org/wiki/Network_effect

²⁸https://en.wikipedia.org/wiki/Network_effect

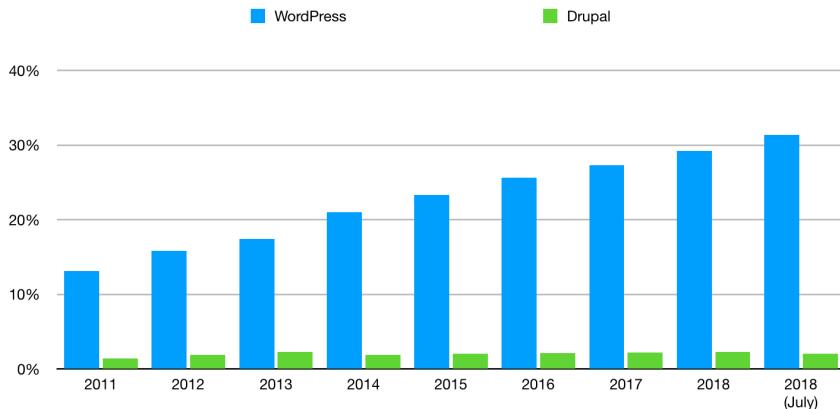

Figure 18.5: Wordpress vs Drupal adoption over 8 years, according to w3techs.com²⁹

And maybe, they aren't comparable: Given the same problems, the people in each ecosystem have approached them and solved them in different ways. And, this has impacted the 'shape' of the abstractions, and the protocols you use in each. Complexity *emerges*, and the ecosystem gets more complex and opinionated, much like the way in which the network of a city will evolve over time in an unpredictable way.

But, by now, if they *are* to be compared side-by-side, WordPress *should be better* due to the sheer number of people in this ecosystem who are...

- Creating web sites.
- Using those sites.
- Submitting bug requests.
- Fixing bugs.
- Writing documentation.
- Building plugins.
- Creating features.
- Improving the core platform.

But, there are two further factors to consider...

1. The Peter Principle

When a tool or platform is popular, it is under pressure to increase in complexity. This is because people are attracted to something useful, and want to extend it to new purposes. This is known as *The Peter Principle*:

“The Peter principle is a concept in management developed by Laurence J. Peter, which observes that people in a hierarchy tend to rise to their ‘level of incompetence’.”

—The Peter Principle, *Wikipedia*³⁰

Although designed for *people*, it can just as easily be applied to any other dependency you can think of. Let’s look at Java³¹ as an example of this.

Java is a very popular platform. Let’s look at how the number of public classes (a good proxy for the boundary) has increased with each release:

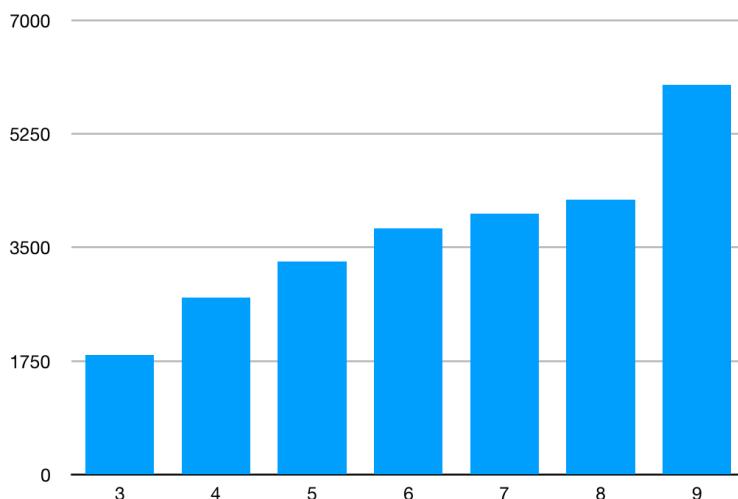

Figure 18.6: Java Public Classes By Version (3-9)

Why does this happen?

- More and more people are using Java for more and more things. It’s popularity begets more popularity.
- Human needs are *fractal* in complexity.
- There is Feature Drift Risk³²: our requirements evolve with time. Android Apps³³ weren’t even a thing when Java 3 came out, for example, yet they are all written in Java now, and Java has had to keep up.

³⁰https://en.wikipedia.org/wiki/Peter_principle

³²[Feature-Risk#feature-drift-risk](#)

³³https://en.wikipedia.org/wiki/Android_software_development

2. Backward Compatibility

As we saw in Software Dependency Risk.

Each new version has a greater functional scope than the one before (pushing back Boundary Risk as there is more functionality to deal with).

Focus vs Overreach

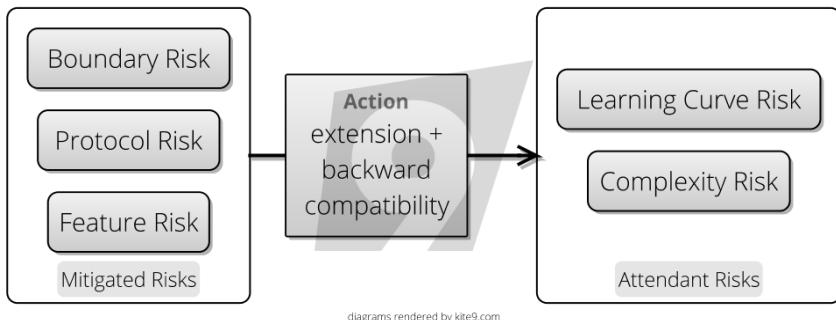

Figure 18.7: The Peter Principle: Backward Compatibility + Extension leads to complexity and learning curve risk

You can see in the diagram the Peter Principle at play: as more responsibility is given to a dependency, the more complex it gets, and the greater the learning curve to work with it. Large ecosystems like Java react to Learning Curve Risk by having copious amounts of literature to read or buy to help, but it is still off-putting.

Because Complexity is Mass. This means that when the world changes, *new* systems will come along to plug the gaps.

This implies a trade-off: - Sometimes it's better to accept the Boundary Risk innate in a smaller system than try to work within the bigger, more complex system.

example:

In the late 80's and 90's there was a massive push towards *building functionality in the database*. Relational Database Management Systems (RDBMSs) were all-in-one solutions, expensive platforms that you purchased and built *everything* inside. However, this dream didn't last:

why? (need some research here).

This tbd

tbd. diagram here.

18.7 Beating Boundary Risk With Standards

Sometimes, technology comes along that allows us to cross boundaries, like a *bridge* or a *road*. This has the effect of making it easy to go from one self-contained ecosystem to another. Going back to WordPress, a simple example might be the Analytics Dashboard³⁴ which provides Google Analytics³⁵ functionality inside WordPress.

I find, a lot of code I write is of this nature: trying to write the *glue code* to join together two different *ecosystems*.

Standards allow us to achieve the same thing, in one of two ways:

- **Mode 1: Abstract over the ecosystems.** Provide a *standard* protocol (a *lingua franca*) which can be converted down into the protocol of any of a number of competing ecosystems.
- **Mode 2: Force adoption.** All of the ecosystems start using the standard for fear of being left out in the cold. Sometimes, a standards body is involved, but other times a “de facto” standard emerges that everyone adopts.

Let’s look at some examples:

- ASCII³⁶: fixed the different-character-sets boundary risk by being a standard that others could adopt. Before everyone agreed on ASCII, copying data from one computer system to another was a massive pain, and would involve some kind of translation. Unicode³⁷ continues this work. (**Mode 1**)
- C³⁸: The C programming language provided a way to get the same programs compiled against different CPU instruction sets, therefore providing some *portability* to code. The problem was, each different operating system would still have its own libraries, and so to support multiple operating systems, you’d have to write code against multiple different libraries. (**Mode 2**)
- Java³⁹ took what C did and went one step further, providing interoperability at the library level. Java code could run anywhere where Java was installed. (**Mode 2**)

³⁴

³⁶<https://en.wikipedia.org/wiki/ASCII>

³⁹[https://en.wikipedia.org/wiki/Java_\(programming_language\)](https://en.wikipedia.org/wiki/Java_(programming_language))

- Internet Protocol⁴⁰: As we saw in Communication Risk⁴¹, the Internet Protocol (IP) is the *lingua franca* of the modern internet. However, at one period of time, there were many competing standards. and IP was the ecosystem that “won”, and was subsequently standardized by the IETF⁴². (**Mode 1**)

18.8 Complex Boundaries

As shown in the above diagram, mitigating Boundary Risk involves taking on complexity. The more Protocol Complexity the bridge will necessarily be.

From examining the [Protocol Risk][br1] at each end of the bridge you are creating, you can get a rough idea of how complex the endeavour will be:

- If it’s low-risk at both ends, you’re probably going to be able to knock it out easily. Like translating a date, or converting one file format to another.
- Where one of the protocols is *evolving*, you’re definitely going to need to keep releasing new versions. The functionality of a Calculator app on my phone remains the same, but new versions have to be released as the phone APIs change, screens change resolution and so on.
- tbd

Object-Relational Mapping

For example, Object Relational Mapping (ORM) like [Java]. Building a *general* library that does this and is useful tbd said:

‘Object/Relational Mapping is the Vietnam of Computer Science’
 - Ted Neward⁴³

This is a particularly difficult problem because the two ecosystems are so *rich* and *complex* in the functionality they expose. But what are the alternatives?

⁴⁰https://en.wikipedia.org/wiki/Internet_Protocol

⁴¹Communication-Risk#protocol-risk

⁴²https://en.wikipedia.org/wiki/Internet_Engineering_Task_Force

Protocol Risk From A	Protocol Risk From B	Resulting Bridge Complexity	Example
Low	Low	Simple	Changing from one date format to another.
High	Low	Moderate	Status Dashboard, tbd
High	High	Complex	Object-Relational Mapping (ORM) Tools, (see below)
High + Evolving	Low	Moderate, Versioned	Simple Phone App, e.g. note-taker or calculator
Evolving	High	Complex	Modern browser (see below)
Evolving	Evolving	Very Complex	Google Search, Scala (see below)

- Either back to building functionality within the database again, using stored procedures
- Building Object Oriented Databases. It's interesting that neither of these really worked out.
- Custom-building the bridge between the systems, one database call at-a-time in your own software.

This is tbd hobson's choice, there is strong debate about whether ORM or not, and clearly will depend on your circumstances.

Scala

Mapping between complex boundaries is especially difficult if the boundaries is an old, large and complex ecosystem, you would imagine that it would have a slow-enough rate of change that abstracting technologies can be built on top of it safely.

Indeed, we see that happening with Clojure and offering compatibility with it.

Scala is arguably the first mainstream language that tried to do the same thing: it is trying to build a Functional Programming paradigm.

The problem faced by Scala, Java moved to include this new functionality too. If they hadn't, the developer community would have slowly drifted away and used Scala instead.

So, in a sense, Scala is a *success story*: they were able to force change to Java. But, once Java had changed, Scala was in the difficult position of having two sets of competing features in the platform: the existing Scala streams, and the new Java streams.

Clojure can interop with Java because on one side, the boundary is simple: lisp is a simple language which lends itself to reimplementation within other platforms. Therefore, the complexity of the bridge is *simple*: all that needs to be provided is a way to call methods from Java to clojure.

Scala and Java have a complex relationship because Scala creates its own complex boundary: it is syntactically and functionally a broad language with lots of features. And so is Java. Mapping from one to the other is therefore

for interop here. Why is one so different from the other?

Browsers

Web browsers are another surprisingly complex boundary. They have to understand the following protocols:

- HTTP
- HTML
- Various image formats
- Javascript for web-page *interactivity*
- CSS for web-page styling, animation and so on.
- . . . and several others.

Handling any one of these protocols alone is a massive endeavour, so browsers are built on top of Software Libraries and so on.

One way of looking at the browser is that it is a *function*, where those elements listed above are the *inputs* to the function, and the output is *what is displayed on the screen*, as shown in the image below.

tbd. browser as a function

There are three specific problems that make this a really complex boundary:

1. All of the standards above are *evolving and improving*. And, although HTML5 is a reasonably well-specified standard, in reality, web pages tend not to adhere exactly to the letter of it. People make mistakes in the HTML they write, and it's up to the browser to try and figure out what they *meant* to write, rather than what they did write. This makes the *input* to the function extremely complex.
2. Similarly, the *output* of the function is not well defined either, and relies a lot on people's *subjective aesthetic judgement*. For example, if you insert a <table> into an HTML page, the specification doesn't say anything about exactly how big the table should be, the size of its borders, the spacing of the content and so on. At least, initially, *none* of this was covered by the HTML Specification specification is over time clearing this up, but it's not *exactly nailed down*, which means . . .
3. That because there are various different browsers (Chrome and each browser has multiple different versions, released over a period of many years, you cannot, as a web-page developer know, *a priori* what your web-page will look like to a user.

As developers trying to build software to be delivered over the internet, this is therefore a source of common Boundary Risk. If you were trying to build software to work in *all browsers* and *all versions*, this problem would be nearly insurmountable. So, in order to tackle this risk, we do the following:

- We pick a small (but commonly used) subset of browsers, and use features from the specifications that we know commonly work in that subset.
- We test across the subset. Again, testing is *harder than it should be*, because of problem 2 above, that the expected output is not exactly defined. This generally means you have to get humans to apply their *subjective aesthetic judgement*, rather than getting machines to do it.
- There is considerable pressure on browser developers to ensure consistency of behaviour across the implementations. If all the browsers work the same, then we don't face the Boundary Risk of having to choose just one to make our software work in. However, it's not always been like this...

18.9 Vendor Lock-In

In the late 1990s, faced with the emergence of the nascent World Wide Web. There are two questions we need to ask about this, from the point-of-view of understanding Boundary Risk:

1. Why was this a successful strategy?
2. Why did they stop doing this?

Let's look at the first question then. Yes, it was a successful strategy. In the 1990s, browser functionality was rudimentary. Developers were *desperate* for more features, and for more control over what appeared on their webpages. And, Internet Explorer (IE): they were able to get more of the functionality they wanted in the browser.

It's worth pointing out, *this was not a new strategy*:

- Processor Chip manufacturers had done something similar in the tbds: by providing features (instructions) on their processors that other vendors didn't have, they made their processors more attractive to system integrators. However, since the instructions were different on different chips, this created Boundary Risk.

- We have two main *mobile* ecosystems: Apple exist which allow you to build
- Currently, Amazon Web Services (AWS). They are both racing to build new functionality, but at the same time it's hard to move from one vendor to another as there is no standardization on the tools.
- As we saw above, Database vendors tried to do the same thing with features in the database. Oracle particularly makes money over differentiating itself from competitors by providing features that other vendors don't have. Tom tbd provides a compelling argument for using these features thus:

tbd.

The next question, is why did Microsoft *stop* pursuing this strategy? It seems that the answer is because they were made to. tbd.

18.10 Everyday Boundary Risks

Boundary Risk occurs all the time. Let's look at some ways:

- **Configuration:** When software has to be deployed onto a server, there has to be configuration (usually on the command line, or via configuration property files) in order to bridge the boundary between the *environment it's running in* and the *software being run*. Often, this is setting up file locations, security keys and passwords, and telling it where to find other files and services.
- **Integration Testing:** Building a unit test is easy. You are generally testing some code you have written, aided with a testing framework. Your code and the framework are both written in the same language, which means low boundary risk. But, to *integration test* you need to step outside this boundary and so it becomes much harder. This is true whether you are integrating with other systems (providing or supplying them with data) or parts of your own system (say testing the client-side and server parts together).
- **User Interface Testing:** If you are supplying a user-interface, then the interface with the user is already a complex, under-specified risky protocol: can you be sure that the screen hasn't got strange glitches, that the mouse moves correctly, that the proportions on the screen are correct on all browsers?

- **Jobs:** When you pick a new technology to learn and add to your CV, it's worth keeping in mind how useful this will be to you in the future. It's career-limiting to be stuck in a dying ecosystem and need to retrain.
- **Teams:** if you're given license to build a new product within an existing team, are you creating Boundary Risk by using tools that the team aren't familiar with?
- **Organisatations:** Getting teams or departments to work with each other often involves breaking down Boundary Risk. Often the departments use different tool-sets or processes, and have different goals making the translation harder. tbd

Boundary Risk and Change

You can't always be sure that a dependency now will always have the same guarantees in the future:

- **Ownership changes** Microsoft. What will happen to the ecosystem around github now?
- **Licensing changes.** (e.g. Oracle⁴⁴ buys Tangosol who make Coherence⁴⁵ for example). Having done this, they increase the licensing costs of Tangosol to huge levels, milking the Cash Cow⁴⁶ of the installed user-base, but ensuring no-one else is likely to use it.
- **Better alternatives become available:** As a real example of this, I began a project in 2016 using Apache Solr⁴⁷. However, in 2018, I would probably use ElasticSearch⁴⁸. In the past, I've built websites using Drupal and then later converted them to use WordPress.

18.11 Patterns In Boundary Risk

In Feature Risk, we saw that the features people need change over time. Let's get more specific about this:

- Human need is Fractal. This means that over time, software products have evolved to more closely map to human needs. Software that would have delighted us ten years ago lacks the sophistication we expect today.
- Software and hardware are both improving with time, due to evolution and the ability to support greater and greater levels of complexity.

⁴⁴<http://oracle.com>

⁴⁵https://en.wikipedia.org/wiki/Oracle_Coherence

⁴⁶

⁴⁷

⁴⁸<https://en.wikipedia.org/wiki/Elasticsearch>

- Abstractions build too. As we saw in Process Risk, we *encapsulate* earlier abstractions in order to build later ones.

If all this is true, the only thing we can expect in the future is that the lifespan of any ecosystem will follow an arc through creation, adoption, growth, use and finally either be abstracted over or abandoned.

tbd diagram.

Although our discipline is a young one, we should probably expect to see “Software Archaeology” in the same way as we see it for biological organisms. Already we can see the dead-ends in the software evolutionary tree: COBOL and BASIC languages, CASE systems. Languages like FORTH live on in PostScript, SQL is still embedded in everything

Boundary risk is *inside* and *outside*

Agency Risk

Coordinating a team. But, people have their own goals, too. Sometimes, the goals harmlessly co-exist with the team's goal, but other times they don't.

This is Agency Risk in order to invest it, but they don't necessarily have your best interests at heart. They may instead elect to invest the money in ways that help them, or outright steal it.

"This dilemma exists in circumstances where agents are motivated to act in their own best interests, which are contrary to those of their principals, and is an example of moral hazard."

—Principal-Agent Problem, Wikipedia¹

The less visibility you have of the agent's activities, the bigger the risk. However, the whole *point* of giving the money to the agent was that you would have to spend less time and effort managing it.

Figure 19.1: Mitigating Agency Risk Through Monitoring

¹https://en.wikipedia.org/wiki/Principalagent_problem

Agency Risk² clearly includes the behaviour of Bad Actors³. But, this is a very strict definition of Agency Risk⁴. In software development, we're not lending each other money, but we are being paid by the project sponsor, so they are assuming Agency Risk⁵ by employing us.

As we saw in the previous chapter on Process Risk doesn't just apply to people: it can apply to *running software* or *whole teams*.

Let's look at some examples of borderline Agency Risk situations, in order to sketch out where the domain of this risk lies.

19.1 Personal Lives

We can't (shouldn't) expect people on a project to sacrifice their personal lives for the success of the project, right? Except that "Crunch Time"⁶ is exactly how some software companies work:

"Game development... requires long working hours and dedication from their employees. Some video game developers (such as Electronic Arts) have been accused of the excessive invocation of "crunch time". "Crunch time" is the point at which the team is thought to be failing to achieve milestones needed to launch a game on schedule. "

—Crunch Time, Wikipedia⁷

People taking time off, going to funerals, looking after sick relatives and so on are all Agency Risk of having *staff* rather than *slaves*.

19.2 The Hero

"The one who stays later than the others is a hero."

—Hero Culture, Ward's Wiki⁸ <!-- tweet-end -->

Conversely, Heroes put in more hours and try to rescue projects single-handedly, often cutting corners like team communication and process in order to get there.

⁷https://en.wikipedia.org/wiki/Video_game_developer#%22Crunch_time%22

⁸<http://wiki.c2.com/?HeroCulture>

Sometimes, projects don't get done without heroes. But other times, the hero has an alternative agenda than just getting the project done:

- A need for control, and for their own vision.
- A preference to work alone.
- A desire for recognition and acclaim from colleagues.
- For the job security of being a Key Man⁹.

A team *can* make use of heroism, but it's a double-edged sword. The hero can becomes a bottleneck.

19.3 Consultancies

When you work with an external consultancy, there is *always* more Agency Risk than with a direct employee. This is because as well as your goals and the employee's goals, there is also the consultancy's goals.

This is a good argument for not using consultancies, but sometimes the technical expertise they bring can outweigh this risk.

Also, try to look for *hungry* consultancies: if you being a happy client is valuable to them, they will work at a discount (either working cheaper, harder or longer or more carefully) as a result.

19.4 CV Building

This is when someone decides that the project needs a dose of "Some Technology X", but in actual fact, this is either completely unhelpful to the project (incurring large amounts of Complexity Risk, or merely less useful than something else).

It's very easy to spot CV building: look for choices of technology that are incongruently complex compared to the problem they solve, and then challenge by suggesting a simpler alternative.

19.5 Career Risk

19.6 Devil Makes Work

Heroes can be useful, but *underused* project members are a nightmare. The problem is, people who are not fully occupied begin to worry that actually,

⁹https://en.wikipedia.org/wiki/Key_person_insurance

the team would be better off without them, and then wonder if their jobs are at risk.

The solution to this is “busy-work”: finding tasks that, at first sight, look useful, and then delivering them in an over-elaborate way (Gold Plating¹⁰) that’ll keep them occupied. This will leave you with more Complexity Risk¹¹ than you had in the first place.

Even if they don’t worry about their jobs, doing this is a way to stave off *boredom*.

19.7 Pet Projects

A project, activity or goal pursued as a personal favourite, rather than because it is generally accepted as necessary or important. -
Pet Project, *Wiktionary*¹²

Sometimes, budget-holders have projects they value more than others without reference to the value placed on them by the business. Perhaps the project has a goal that aligns closely with the budget holder’s passions, or its related to work they were previously responsible for.

Working on a pet project usually means you get lots of attention (and more than enough budget), but due to Map and Territory Risk, it can fall apart very quickly under scrutiny.

19.8 Morale Risk

Morale, also known as Esprit de Corps is the capacity of a group’s members to retain belief in an institution or goal, particularly in the face of opposition or hardship - Morale, *Wikipedia*¹³

Sometimes, the morale of the team or individuals within it dips, leading to lack of motivation. Morale Risk might be caused by:

- External factors: Perhaps the employees’ dog has died, or they’re simply tired of the industry, or are not feeling challenged.

¹⁰[https://en.wikipedia.org/wiki/Gold_plating_\(software_engineering\)](https://en.wikipedia.org/wiki/Gold_plating_(software_engineering))

¹¹Complexity-Risk

¹²https://en.wiktionary.org/wiki/pet_project

¹³<https://en.wikipedia.org/wiki/Morale>

- If the team don't believe a goal is achievable, they won't commit their full effort to it. This might be due to a difference in the evaluation of the risks on the project between the team members and the leader.
- If the goal isn't considered sufficiently worthy, or the team isn't sufficiently valued.
- In military science, a second meaning of morale is how well supplied and equipped a unit is. This would also seem like a useful reference point for IT projects. If teams are under-staffed or under-equipped, this will impact on motivation too.

19.9 Hubris & Ego

It seems strange that humans are over-confident. You would have thought that evolution would drive out this trait but apparently it's not so:

"Now, new computer simulations show that a false sense of optimism, whether when deciding to go to war or investing in a new stock, can often improve your chances of winning."

—Evolution of Narcissism, *National Geographic*¹⁴

In any case, humans have lots of self-destructive tendencies that *haven't* been evolved away, and we get by.

Development is a craft, and ideally, we'd like developers to take pride in their work. Too little pride means lack of care, but too much pride is *hubris*, and the belief that you are better than you really are. Who does hubris benefit? Certainly not the team, and not the goal, because hubris blinds the team to hidden risks that they really should have seen.

Although over-confidence might be a useful trait when bargaining with other humans, the thesis of everything so far is that Meeting Reality will punish your over-confidence again and again.

Perhaps it's a little unfair to draw out one human characteristic for attention. After all, we are riddled with biases

19.10 Software Processes And Teams

Agency Risk doesn't just refer to people - it refers to anything which has agency over its actions.

¹⁴<https://news.nationalgeographic.com/news/2011/09/110914-optimism-narcissism-overconfidence-hubris-evolution-science-nature/>

“Agency is the capacity of an actor to act in a given environment... Agency may either be classified as unconscious, involuntary behavior, or purposeful, goal directed activity (intentional action).”

—Agency, Wikipedia¹⁵

There is significant Agency Risk in running software *at all*. Since computer systems follow rules we set for them, we shouldn't be surprised when those rules have exceptions that lead to disaster. For example:

- A process continually writing log files until the disks fill up, crashing the system.
- Bugs causing data to get corrupted, causing financial loss.
- Malware infecting a system, and sending your passwords and data to undesirables.

Agency Risk that don't align with those of the overall organisation. For example:

- A team introduces excessive Bureaucracy in order to avoid work it doesn't like.
- A team gets obsessed with a particular technology, or their own internal process improvement, at the expense of delivering business value.
- A marginalised team forces their services on other teams in the name of “consistency”. (This can happen a lot with “Architecture”, “Branding” and “Testing” teams, sometimes for the better, sometimes for the worse.)

19.11 It's About Goals

We've looked here at some illustrative examples of Agency Risk between the different agents, whether they are *people, teams or software*.

So, having looked at agents *individually*, it's time to look more closely at Goals when aligning them amongst multiple agents.

On to Coordination Risk...

¹⁵[https://en.wikipedia.org/wiki/Agency_\(philosophy\)](https://en.wikipedia.org/wiki/Agency_(philosophy))

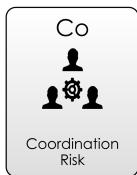

- Risks due to the fact that things you depend on have agency, and they have their own goals to pursue.

Figure 19.2: Agency Risk

Coordination Risk

Coordination Risk is embodied in the phrase “Too Many Cooks Spoil The Broth”: more people, opinions or agents often make results worse.

- Risks that a group of agents cannot work together in a mutually beneficial way, and their behaviour devolves into competition.

Figure 20.1: Coordination Risk

As in Agency Risk¹, we are going to use the term *agent*, which refers to anything with agency² in a system to decide it's own fate. That is, an agent has an Internal Model³, and can take actions⁴ based on it. Here, we're going to work on the assumption that the agents *are* working towards a common Goal⁵, even though in reality it's not always the case, as we saw in the chapter on Agency Risk⁶.

In this chapter, we'll first build up A Model Of Coordination Risk . We'll look at: - Team Decision Making, - Living Organisms, - Larger Organisations and the staff within them, - and Software Processes.

⁶Agency-Risk

... and we'll consider how Coordination Risk is a problem at each scale.

But for now, let's crack on and examine where Coordination Risk comes from.

20.1 A Model Of Coordination Risk

Earlier, in Dependency Risk: other parties want to use them in a different way.

Competition

The basic problem of Coordination Risk, which is wasteful.

Why is this wasteful?

One argument could come from Diminishing Returns⁷, which says that the earlier units of a resource (say, chocolate bars) give you more benefit than later ones.

We can see this in the graph below. Let's say A and B compete over a resource, of which there are 5 units available. For every extra A takes, B loses one. The X axis shows A's consumption of the resource, so the biggest benefit to A is in the consumption of the first unit.

As you can see, by *sharing*, it's possible that the *total benefit* is greater than it can be for either individual. But sharing requires coordination. Further, the more competitors involved, the *worse* a winner-take-all outcome is for total benefit.

Just two things are needed for competition to occur:

- Individual agents, trying to achieve Goals.
- Scarce Resources, which the agents want to use as Dependencies.

Coordination via Communication

The only way that the agents can move away from competition towards coordination is via Communication, and this is where their coordination problems begin.

You might think, therefore, that this is just another type of Communication Risk. If they coordinate, and leave in an orderly fashion, they might all get

⁷https://en.wikipedia.org/wiki/Diminishing_returns

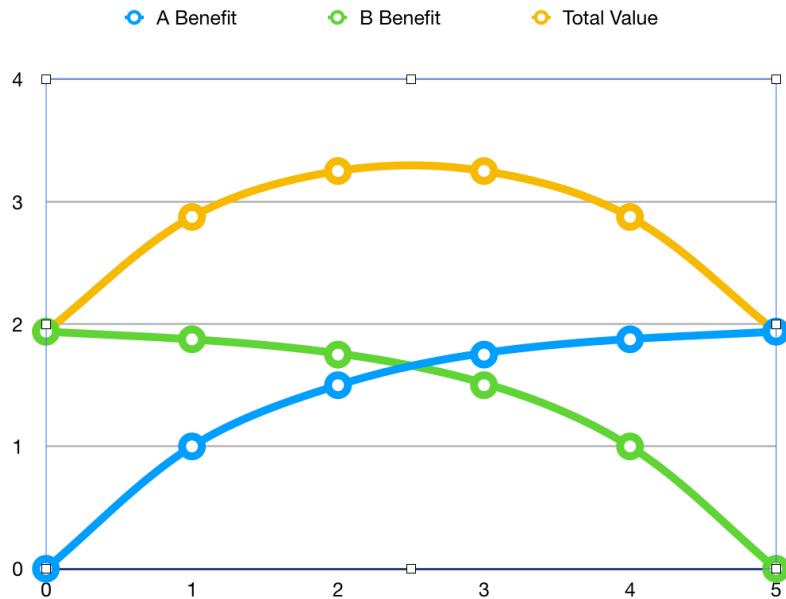

Figure 20.2: Sharing Resources. 5 units are available, and the X axis shows A's consumption of the resource. B gets whatever remains. Total benefit is maximised somewhere in the middle

out. If they don't, and there's a scramble for the door, more people might die.

But commonly, Coordination Risk available for communication.

20.2 Problems Of Coordination

Let's unpack this idea, and review some classic problems of coordination, none of which can be addressed without good communication:

1. **Merging Data.** If you are familiar with the source code control system, Git⁸, you will know that this is a *distributed* version control system. That means that two or more people can propose changes to the same files without knowing about each other. This means that at some later time, Git⁹ then has to merge (or reconcile) these changes together. Git is very good at doing this automatically, but sometimes, different people

⁸<https://en.wikipedia.org/wiki/Git>

⁹<https://en.wikipedia.org/wiki/Git>

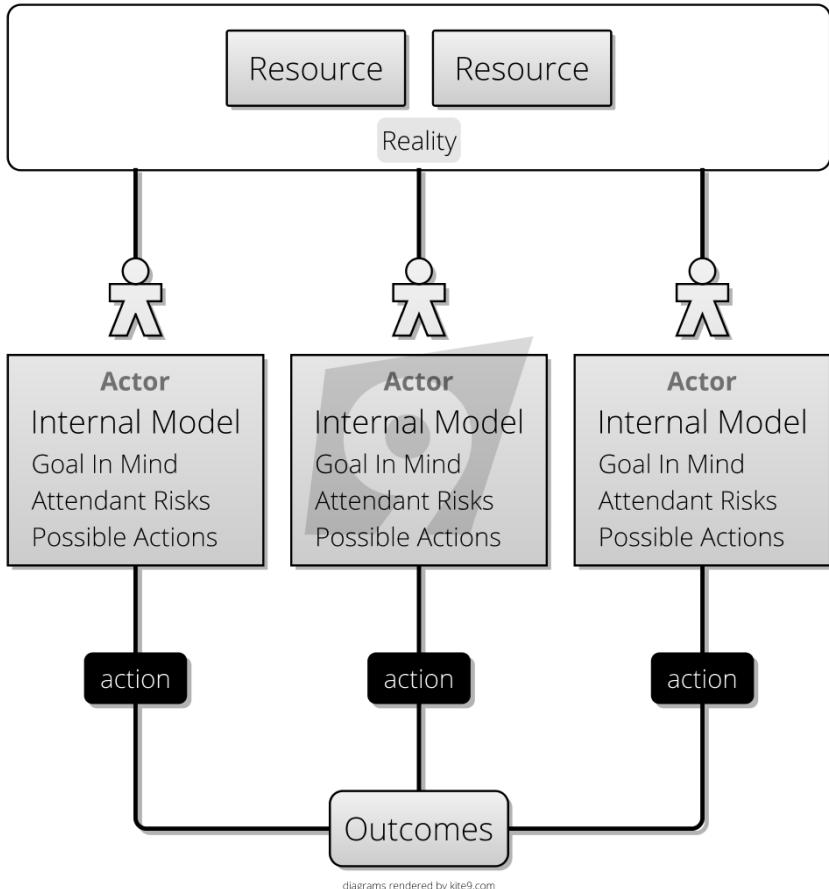

Figure 20.3: A model of competition: scarce resources, and individual agents competing for them.

can independently change the same lines of code and these will have to be merged manually. In this case, a human arbitrator “resolves” the difference, either by combining the two changes or picking a winner.

2. **Consensus.** Making group decisions (as in elections) is often decided by votes. But having a vote is a coordination issue, and requires that everyone has been told the rules:

- Where will the vote be held?
- How long do you provide for the vote?
- What do you do about absentees?
- What if people change their minds in the light of new information?

- How do you ensure everyone has enough information to make a good decision?
3. **Factions.** Sometimes, it's hard to coordinate large groups at the same time, and "factions" can occur. That the world isn't a single big country is probably partly a testament to this: countries are frequently separated by geographic features that prevent the easy flow of communication (and force). We can also see this in distributed systems, with the "split brain"¹⁰ problem. This is where a network of processes becomes disconnected (usually due to a network failure between data centers), and you end up with two, smaller networks with different knowledge. We'll address in more depth later.
 4. Resource Allocation¹¹: Ensuring that the right people are doing the right work, or the right resources are given to the right people is a coordination issue. On a grand scale, we have Logistics¹², and Economic Systems¹³. On a small scale, the office's *room booking system* solves the coordination issue of who gets a meeting room using a first-come-first-served booking algorithm.
 5. Deadlock¹⁴: Deadlock refers to a situation where, in an environment where multiple parallel processes are running, the processing stops and no-one can make progress because the resources each process needs are being reserved by another process. This is a specific issue in Resource Allocation¹⁵, but it's one we're familiar with in the computer science industry. Compare with Gridlock¹⁶, where traffic can't move because other traffic is occupying the space it wants to move to already.
 6. Race Conditions¹⁷: A race condition is where we can't be sure of the result of a calculation, because it is dependent on the ordering of events within a system. For example, two separate threads writing the same memory at the same time (one ignoring and over-writing the work of the other) is a race.
 7. **Contention:** Where there is Scarcity Risk itself. However if it isn't, it's the *users* of the dependency who'll need to coordinate to use the resource fairly, again, by communicating with each other.

20.3 Team Decision Making

Within a team, Coordination Risk is worse on projects with more members, and worse in organizations with more staff.

If you are engaged in a solo project, do you suffer from Coordination Risk¹⁸ at all? Maybe: sometimes, you can feel “conflicted” about the best way to solve a problem. And weirdly, usually *not thinking about it* helps. Sleeping too. (Rich Hickey calls this “Hammock Driven Development¹⁹”). This is probably because, unbeknownst to you, your subconscious is furiously communicating internally, trying to resolve these conflicts itself, and will let you know when it’s come to a resolution.

Vroom and Yetton²⁰ introduced a model of group decision making which delineated five different styles of decision making within a team. These are summarised in the table below (AI, AII, CI, CII, GII). To this, I have added a sixth (UI), which is the *uncoordinated* option, where everyone competes. In the accompanying diagrams I have adopted the following convention: - Thin lines with arrow-heads show a flow of *information*, either one-way or two-way. - Thick lines show a flow of *opinion*. - Boxes with corners are *decision makers*, whereas curved corners don’t have a part in the decision.

At the top, you have the *least* consultative styles, and at the bottom, the *most*. At the top, decisions are made with just the leader’s Internal Model of the rest of the team are increasingly brought into play.

The decisions at the top are faster, but don’t do much for mitigating **Coordination Risk**. The ones below take longer, (incurring Schedule Risk).

The trick is to be able to tell which approach is suitable at which time. Everyone is expected to make decisions *within their realm of expertise*: you can’t have developers continually calling meetings to discuss whether they should be using an Abstract Factory²¹ or a Factory Method²², this would waste time. The critical question is therefore, “what’s the biggest risk?” - Is the Coordination Risk too. - Is the Schedule Risk greater? If you have a 1-hour meeting with eight people to decide a decision, that’s *one man day* gone right there: group decision making is *expensive*.

Hopefully, this model shows how *organisation* can reduce Coordination Risk:

Staff As Agents

Staff in a team have a dual nature: they are **Agents** and **Resources** at the same time. The team depends over their own actions.

Part of Coordination Risk. So it's worth considering how varied people's models can be: - Different skill levels - Different experiences - Expertise in different areas - Preferences - Personalities

The job of harmonizing this on a project would seem to fall to the team leader, but actually people are self-organising to some extent. This process is called Team Development²³:

“The forming–storming–norming–performing model of group development was first proposed by Bruce Tuckman in 1965, who said that these phases are all necessary and inevitable in order for the team to grow, face up to challenges, tackle problems, find solutions, plan work, and deliver results.”

—Tuckman’s Stages Of Group Development, Wikipedia²⁴

Specifically, this describes a process whereby a new group will form and then be required to work together. In the process, they will have many *disputes*. Ideally, the group will resolve these disputes internally and emerge as a *Team*, with a common Goal In Mind.

They can be encouraged with orthogonal practices such as team-building exercises²⁵ (generally, submitting everyone to extreme experiences in order to bond them together). With enough communication bandwidth and detente, a motivated team will self-organise code reviews, information exchange and improve their practices.

As described above, the job of Coordination issues like:

- People leaving, taking their Internal Models.
- People requiring external training, to understand new tools and techniques Learning-Curve Risk.
- People being protective about their knowledge in order to protect their jobs Agency Risk.
- Where there are mixed ability levels, senior developers not helping juniors as it “slows them down”.
- People not getting on and not helping each other.

"As a rough rule, three programmers organised into a team can do only twice the work of a single programmer of the same ability - because of time spent on coordination problems."

Gerald Wienberg, The Psychology of Computer Programming²⁶

20.4 In Living Organisms

Vroom and Yetton's organisational style isn't relevant to just teams of people. We can see it in the natural world too. Although *the majority* of cellular life on earth (by weight) is single celled organisms²⁷, the existence of *humans* (to pick a single example) demonstrates that sometimes it's better to try to mitigate Coordination Risk²⁸ and work as a team, accepting the Complexity Risk²⁹ and Communication Risk³⁰ this entails. As soon as cells start working together, they either need to pass *resources* between them, or *control* and *feedback*.

For example, in the human body, we have various systems³¹:

- The Respiratory System³² which is responsible for ensuring that Red Blood Cells³³ are replenished with Oxygen, as well as disposing of Carbon Dioxide.
- The Digestive System³⁴ which is responsible for extracting nutrition from food and putting them in our Blood Plasma³⁵.
- The Circulatory System³⁶ which is responsible for moving blood cells to all the rest of the body.
- The Nervous System³⁷ which is responsible for collecting information from all the parts of the body, dealing with it in the Brain³⁸ and issuing commands.
- The Motor System³⁹ which contains muscles and bones, and allows us to move about.

³⁷https://en.wikipedia.org/wiki/Nervous_system

³⁸<https://en.wikipedia.org/wiki/Brain>

³⁹https://en.wikipedia.org/wiki/Motor_system

... and many others. Each of these systems contains organs, which contain tissues, which contain cells of different types. (Even cells are complex systems containing multiple different, communicating sub-systems.) There is huge Complexity Risk⁴⁰ here: the entire organism fails if one of these systems fail (they are Single Points Of Failure⁴¹, although we can get by despite the failure of one lung or one leg say).

Some argue⁴² that the human nervous system is the most complex known artifact in the universe: there is huge attendant Communication Risk⁴³ to running the human body. But, given the success of humanity as a species, you must conclude that these steps on the evolutionary Risk Landscape⁴⁴ have benefitted us in our ecological niche.

The key observation from looking at biology is this: most of the cells in the human body *don't get a vote*. Muscles in the motor system have an **AI** or **AII** relationship with the brain - they do what they are told, but there are often nerves to report pain back. The only place where **CII** or **GII** *could* occur is in our brains, when we try to make a decision and weigh up the pros and cons.

This means that there is a deal: *most* of the cells in our body accede control of their destiny to "the system". Living within the system of the human body is a better option than going it alone. Occasionally, due to mutation, we can end up with Cancer⁴⁵, which is where one cell genetically "forgets" its purpose in the whole system and goes back to selfish individual self-replication (**UI**). We have White Blood Cells⁴⁶ in the body to shut down this kind of behaviour and try to kill the rogue cells. In the same way, society has a police force to stop undesirable behaviour amongst its citizens.

20.5 Large Organisations

Working in a large organisation often feels like being a cell in a larger organism. Just as cells live and die, but the organism goes on, in the same way, workers come and go from a large company but the organisation goes on. By working in an organisation, we give up self-control and competition and accept **AI** and **AII** power structures above us, but we trust that there is symbiotic value creation on both sides of the employment deal.

Figure 20.6: Hierarchy of Function in the Human Body

Less consultative decision making styles are more appropriate than when we don't have the luxury of high-bandwidth channels for discussion, or when the number of parties rises above a room-full of people. As you can see from the table above, for **CII** and **GII** decision-making styles, the amount of communication increases non-linearly with the number of participants, so we need something simpler. As we saw in the Complexity Risk chapter, hierarchies are an excellent way of economizing on number of different communication channels, and we use these frequently when there are lots of parties to coordinate.

In large organisations, teams are created and leaders chosen for those teams precisely to mitigate Communication Risk. We're all familiar with this: control of the team is ceded to the leader, who takes on the role of 'handing down' direction from above, but also 'reporting up' issues that cannot be resolved within the team. In Vroom and Yetton's model, this is moving from a **GII** or **CII** to an **AI** or **AII** style of leadership.

As shown in the diagram above, we end up with a hierarchy of groups, each having its own decision-making style. The team leader at the bottom level is a *decision maker* within his team, but moving up, doesn't have decision making power in the next team up.. and so on.

Sometimes, parts of an organisation are encouraged *not* to coordinate, but to compete. In the diagram above, we have an M-Form⁴⁷ organisation, composed of *competing divisions*.

Clearly, this is just a *model*, it's not set in stone and decision making styles usually change from day-to-day and decision to decision. The same is not true in our software - *rules are rules*.

20.6 In Software Processes

It should be pretty clear that we are applying the Scale Invariance.

As before, in order to face Coordination Risk.

CAP Theorem

The CAP Theorem⁴⁸ has a lot to say about Coordination Risk⁴⁹. Imagine talking to a distributed database, where your request (*read* or *write*) can be handled by one of many agents.

⁴⁷https://en.wikipedia.org/wiki/Multi-divisional_form

⁴⁸https://en.wikipedia.org/wiki/CAP_theorem

⁴⁹Coordination-Risk

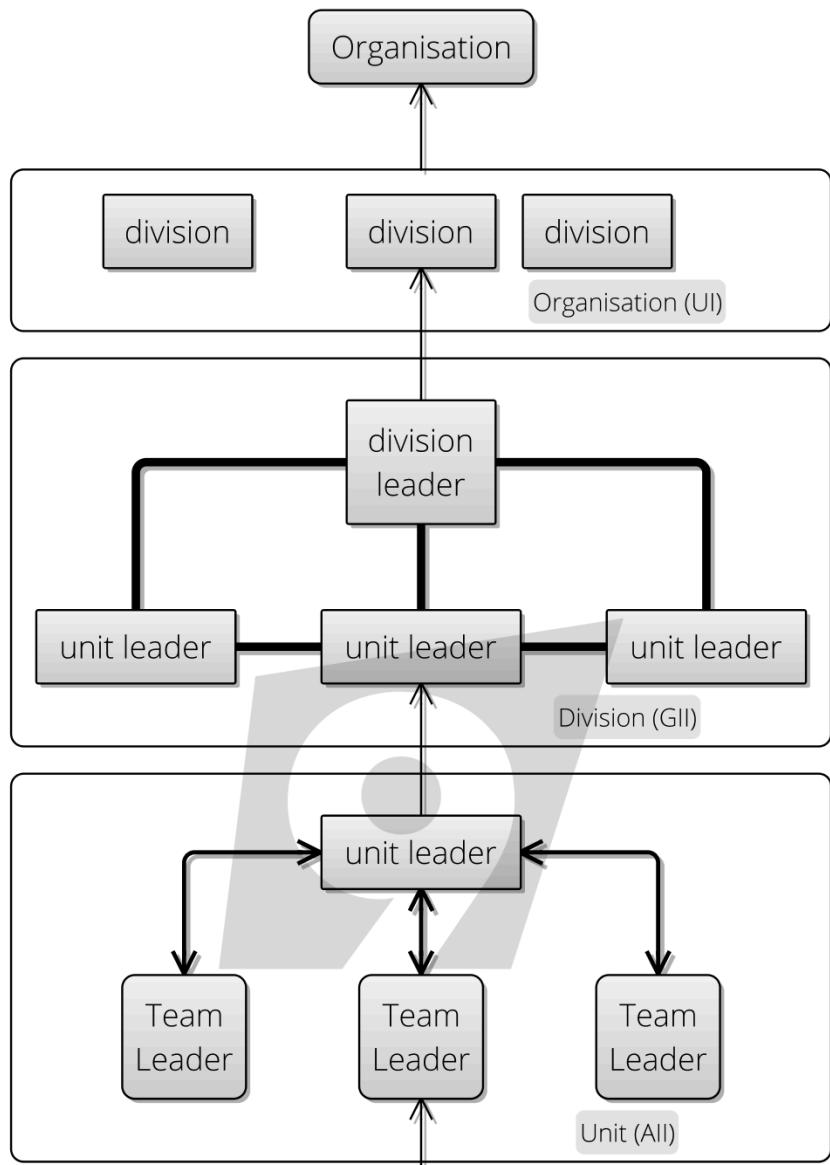

Figure 20.7: Hierarchy of Function in an Organisation

In the diagram below, we have just two agents 1 and 2, in order to keep things simple. User A *writes something* to the database, then User B *reads it back* afterwards.

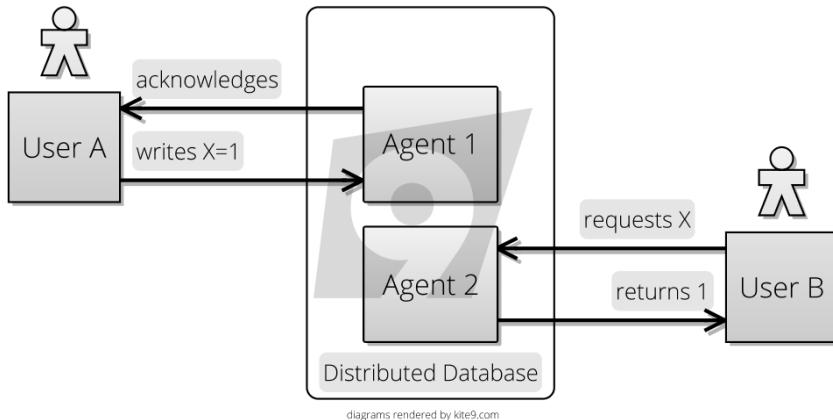

Figure 20.8: User A and User B are both using a distributed database, managed by Agents 1 and 2, whom each have their own Internal Model

According to the CAP Theorem⁵⁰, there are three properties we could desire in such a system:

- **Consistency:** Every read receives the most recent value from the last write.
- **Availability:** Every request receives a response.
- **Partition tolerance:** The system can operate despite the isolation (lack of communication with) some of its agents.

The CAP Theorem⁵¹ states that this is a Trilemma⁵². That is, you can only have two out of the three properties.

There are plenty of resources on the internet that discuss this in depth, but let's just illustrate with some diagrams to show how this plays out. In our diagram example, we'll say that *any* agent can receive the read or write. So this might be a GII decision making system, because all the agents are going to need to coordinate to figure out what the right value is to return for a read, and what the last value written was. In these, the last write (setting X to 1)

⁵⁰https://en.wikipedia.org/wiki/CAP_theorem

⁵¹https://en.wikipedia.org/wiki/CAP_theorem

⁵²<https://en.wikipedia.org/wiki/Trilemma>

was sent to Agent 1 which then becomes *isolated*, and can't be communicated with, due to network failure. What will User B get back?

With an AP System

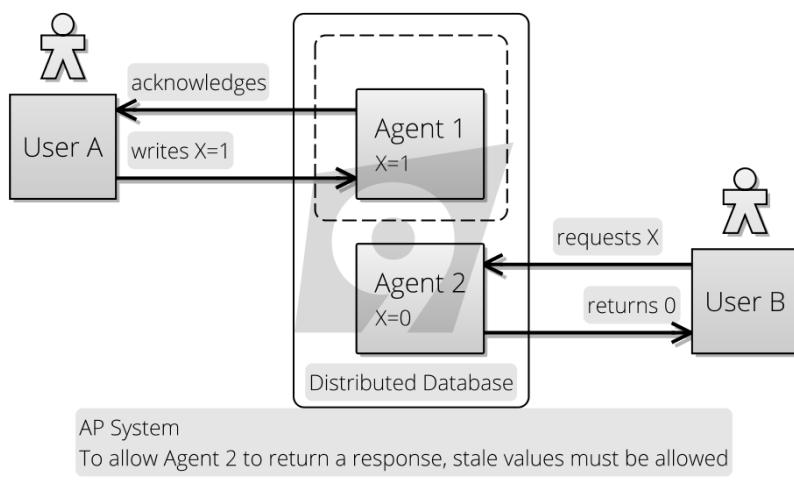

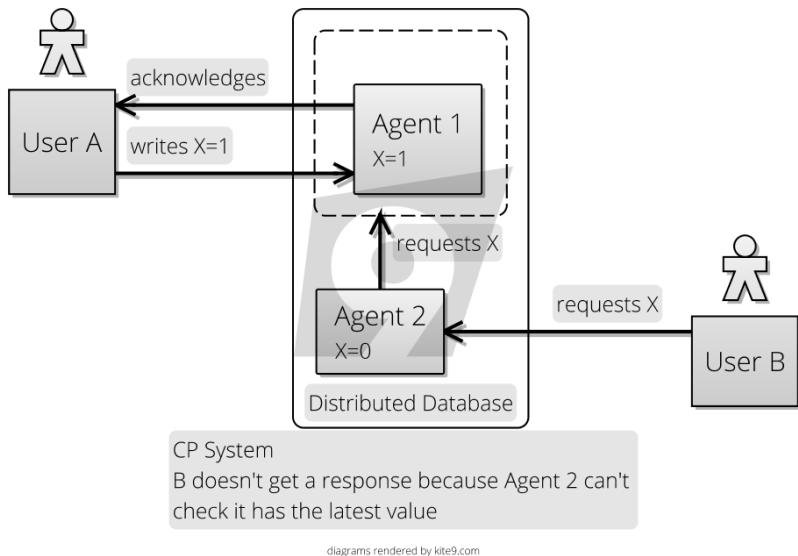

Figure 20.9: In an AP system, the User B will get back a stale value for X

With AP, you can see that User B is getting back a *stale value*. AP scenarios lead to Race Conditions⁵³: Agent 1's availability determines what value User B gets back.

⁵³https://en.wikipedia.org/wiki/Race_condition

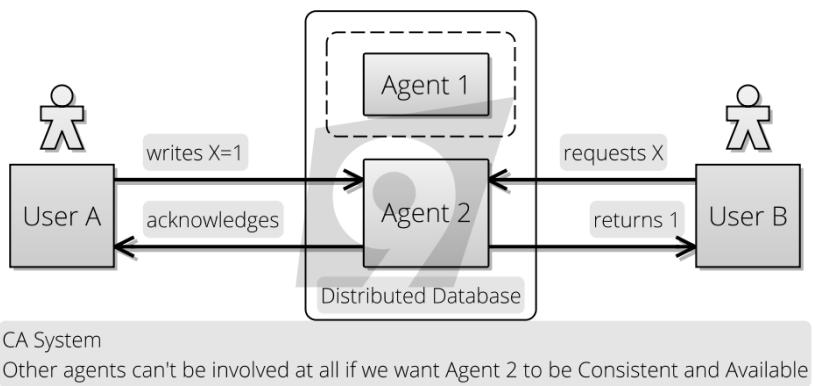

With an CP System

diagrams rendered by kite9.com

Where Agent 2 is left waiting for Agent 1 to re-appear, we are *blocked*. So CP systems lead to Deadlock⁵⁴ scenarios.

With an CA System

diagrams rendered by kite9.com

Figure 20.10: In an CA system, we can't have partition tolerance, so in order to be consistent a single Agent has to do all the work

⁵⁴<https://en.wikipedia.org/wiki/Deadlock>

Finally, if we have a CA system, we are essentially saying that *only one agent is doing the work*. (You can't partition a single agent, after all). But this leads to Resource Allocation⁵⁵ and **Contention** around use of the scarce resource of Agent 2's attention. (Both Coordination Risk⁵⁶ issues we met earlier.)

Some Real-Life Examples

This sets an upper bound on Coordination Risk: we *can't* get rid of it completely in a software system, -or- a system on any other scale. Fundamentally, coordination problems are inescapable at some level. The best we can do is mitigate it by agreeing on protocols and doing lots of communication.

Let's look at some real-life examples of how this manifests in software.

ZooKeeper

First, ZooKeeper⁵⁷ is an Open-Source datastore, which is used a lot for coordinating a distributed systems, and storing things like configuration information across them. If the configuration of a distributed system gets changed, it's important that *all of the agents in the system know about it*, otherwise... disaster.

This *seems* trivial, but it quickly gets out-of-hand: what happens if only some of the agents receive the new information? What happens if a datacentre gets disconnected while the update is happening? There are lots of edge-cases.

ZooKeeper handles this by communicating inter-agent with its own protocol. It elects a **master agent** (via voting), turning it into an AI-style team. If the master is lost for some reason, a new leader is elected. *Writes* are then coordinated via the **master agent** who makes sure that a *majority of agents* have received and stored the configuration change before telling the user that the transaction is complete. Therefore, ZooKeeper is a CP system.

Git

Second, git⁵⁸ is a (mainly) write-only ledger of source changes. However, as we already discussed above, where different agents make incompatible changes, someone has to decide how to resolve the conflicts so that we have a single source of truth.

The Coordination Risk just *doesn't go away*.

⁵⁶Coordination-Risk

⁵⁷<https://zookeeper.apache.org>

⁵⁸<https://en.wikipedia.org/wiki/Git>

Since multiple users can make all the changes they like locally, and merge them later, Git is an AP system: individual users may have *wildly* different ideas about what the source looks like until the merge is complete.

Bitcoin

Finally, Bitcoin (BTC)⁵⁹ is a write-only distributed ledger⁶⁰, where agents *compete* to mine BTC, but also at the same time record transactions on the ledger. BTC is also AP, in a similar way to Git. But new changes can only be appended if you have the latest version of the ledger. If you append to an out-of-date ledger, your work will be lost.

Because it's based on outright competition, if someone beats you to completing a mining task, then your work is wasted. So, there is *huge* Coordination Risk.

For this reason, BTC agents coordinate⁶¹ into mining consortia⁶², so they can avoid working on the same tasks at the same time. But this in itself is a problem, because the whole *point* of BTC is that it's competitive, and no one entity has control. So, mining pools tend to stop growing before they reach 50% of the BTC network's processing power. Taking control would be politically disastrous⁶³ and confidence in the currency (such as there is) would likely be lost.

20.7 Communication Is For Coordination

So, now we have a fundamental limit on how much Coordination Risk within teams of people, organisations or living organisms, so it's the case in software.

Earlier in this chapter, we questioned whether Coordination Risk. However, it should be clear after looking at the examples of competition, cellular life and Vroom and Yetton's Model that this is exactly *backwards*:

- Most single-celled life has no need for communication: it simply competes for the available resources. If it lacks anything it needs, it dies.
- There are *no* lines of communication on the **UI** decision-type. It's only when we want to avoid competition, by sharing resources and working towards common goals that we need to communicate.
- Therefore, the whole point of communication *is for coordination*.

In the next chapter, Map And Territory Risk, we're going to look at some new ways in which systems can fail, despite their attempts to coordinate.

Map And Territory Risk

As we discussed in the chapter on Abstraction, our understanding of the world is entirely informed by the names we give things and the abstractions we create.

(In the same way, **Risk-First** is about *identifying patterns* within software development and calling them out.)

Our Internal Models are a model of the world based on these patterns, and their relationships.

So there is a translation going on here: observations about the arrangement of *atoms* in the world get turned into patterns of *information* (measured in bits and bytes).

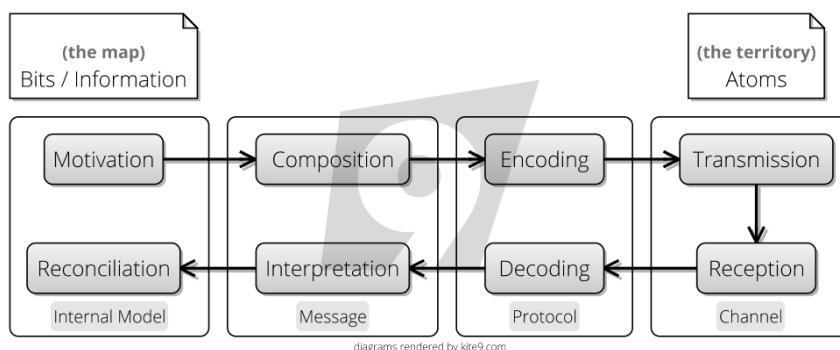

Figure 21.1: Maps and Territories, and Communication happening between them

Map And Territory Risk rather than reality itself. It comes from the expression “Confusing the Map for the Territory”, attributed to Alfred Korzybski:

"Polish-American scientist and philosopher Alfred Korzybski remarked that "the map is not the territory" and that "the word is not the thing", encapsulating his view that an abstraction derived from something, or a reaction to it, is not the thing itself. Korzybski held that many people *do* confuse maps with territories, that is, confuse models of reality with reality itself."

—Map-Territory Relation, Wikipedia¹

In this chapter, we're going to make a case for analysing Map and Territory Risk within the context of **machines, people, hierarchies and markets**.

tbd - diagram of how our actions are based on the map, not the territory.

21.1 Fitness

In the picture shown here, from the Telegraph newspaper, the driver *trusted* the SatNav to such an extent that he didn't pay attention to the road-signs around him, and ended up getting stuck.

This wasn't borne of stupidity, but experience: SatNavs are pretty reliable. *So many times* the SatNav had been right, that the driver stopped *questioning its fallibility*.

So, there are two Map and Territory Risks here:

- The Internal Model of the *SatNav* contained information that was wrong: the track had been marked up as a road, rather than a path.
- The Internal Model of the *driver* was wrong: his abstraction of "the SatNav is always right" turned out to be only *mostly* accurate.

21.2 Internal Models as Dependencies, Features

What are the risks at play here? We've already looked in detail at the Dependency Risks too.

We could argue that the SatNav and the Driver's Internal Model, you can't buy a new one, but you may learn to *trust certain abstractions less*, as this driver did.

In the Feature Risk on three axes: **Fitness, Evolution and Audience**.

Lets do this again and see how each type of Feature Risk:

As with Features has at least these three dimensions:

¹https://en.wikipedia.org/wiki/Mapterritory_relation

A van got stuck on a narrow footpath when the driver took a wrong turn while blindly following his sat-nav. Photo: MEN

Figure 21.2: Sat Nav Blunder Sends Asda Van Crashing Narrow Footpath - Telegraph Newspaper

- **Fitness:** as discussed above with the SatNav example, this is how closely the information matches reality, and how *useful that is to us* (models that contain too much detail are as bad as models with too little).
- **Audience:** is all about how a piece of information is *shared* between many Internal Models, and it's this we are going to address further now.
- **Evolution:** is all about how Internal Models change when they meet reality, and we'll cover that last.

21.3 Audience

We already know a lot about Internal Models and audience, as these have been the subject of previous chapters:

- We know from looking at Communication Risk.
- We know from Coordination Risk so that they cooperate.
- Job markets show us that there is demand for people with certain *skills*. This demonstrates to us that Market Risk.

Dimension	Feature Risk	Examples
Fit	 Fi Fit Risk	<ul style="list-style-type: none"> A filing cabinet containing too much junk. Learning things that aren't useful. Knowing how a car works, but actually needing to know how to drive. Knowing how to program in one language, when another would be more appropriate. Sat Nav had the wrong route. Not quite remembering a recipe properly.
Audience	 FD Feature Diff. Risk	<ul style="list-style-type: none"> Knowing outdated tools. Writing last year's date on the cheque. The bank sending letters to your old address. Forgetting things
Evolution	 R Regression Risk	<ul style="list-style-type: none"> Memes. Demand for courses. Metrics. Echo Chambers Shared values which exclude certain people. Ideas going "out of fashion".

Figure 21.3: Feature Risk, as manifested in the Internal Model

... And, we're all familiar with *memes*:

"A meme acts as a unit for carrying cultural ideas, symbols, or practices, that can be transmitted from one mind to another through writing, speech, gestures, rituals, or other imitable phenomena with a mimicked theme."

—Meme, Wikipedia²

Therefore, we should be able to track the rise-and-fall of *ideas* much as we can track stock prices. And in effect, this is what Google Trends³ does. In the chart below, we can see the relative popularity of two search terms over time. This is probably as good an indicator as any of the audience for an abstraction at any point in time.

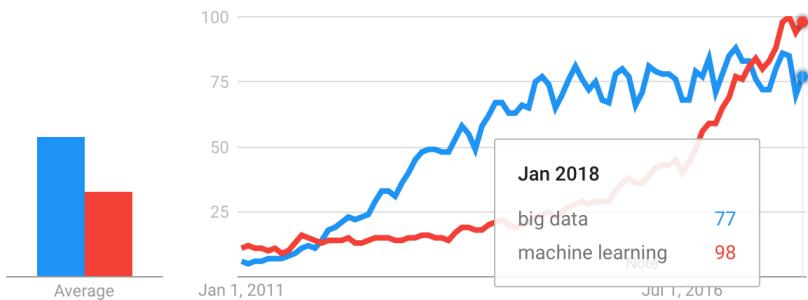

Figure 21.4: Relative popularity of "Machine Learning" and "Big Data" as search terms on Google Trends, 2011-2018

Example: Hype Cycles

Most ideas (and most products) have a slow, hard climb to wide-scale adoption. But some ideas seem to disperse much more rapidly and are picked up quickly because they are exciting and promising, having greater "memetic potential" within society. One way this evolution manifests itself in the world is through the Hype Cycle⁴:

²<https://en.wikipedia.org/wiki/Meme>

³<https://trends.google.com>

⁴https://en.wikipedia.org/wiki/Hype_cycle

"The hype cycle is a branded graphical presentation developed and used by the American research, advisory and information technology firm Gartner, for representing the maturity, adoption and social application of specific technologies. The hype cycle provides a graphical and conceptual presentation of the maturity of emerging technologies through five phases."

—Hype Cycle, Wikipedia⁵

The five phases (and the "Hype" itself) are shown in the chart below, with the thick black line being "Hype":

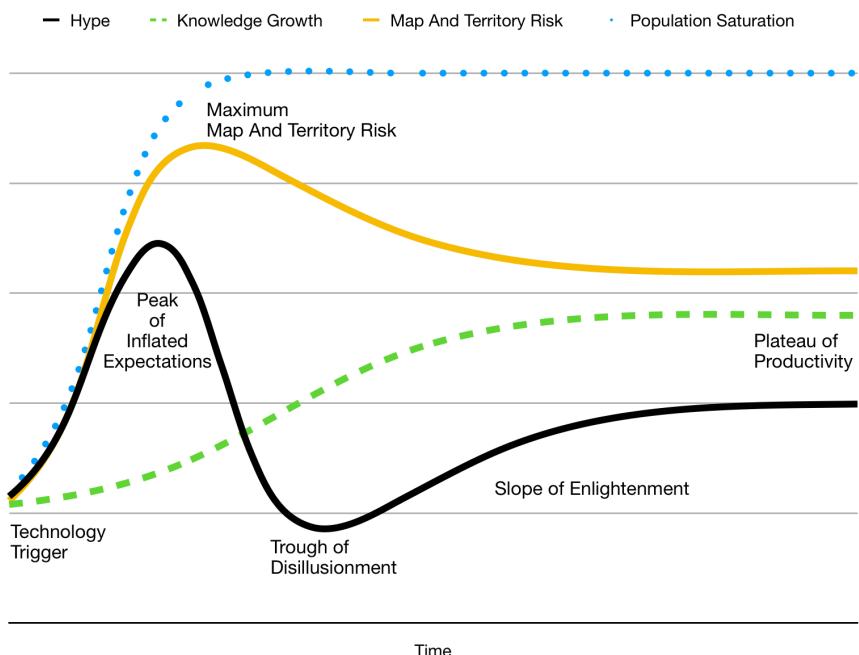

Figure 21.5: Hype Cycle, along with Map & Territory Risk

Also in this diagram we are showing where the hype originates:

- The **saturation** of the idea within the audience (a dotted line).
- The **amount known** about the idea by the audience (a Learning Curve).

Both of these are modelled with Cumulative Distribution⁶ curves. From these two things, we can figure out where our maximum Map and Territory

⁵https://en.wikipedia.org/wiki/Hype_cycle

⁶https://en.wikipedia.org/wiki/Cumulative_distribution_function#Use_in_statistical_analysis

Risk⁷ lies: it's the point where awareness of an idea is furthest from the understanding of it. This acts as a "brake" on the **hype** around the idea, corresponding to the "Trough of Disillusionment".

Where the **saturation** and **knowledge** grow together, there is no spike in Map and Territory Risk and we don't see the corresponding "Trough of Disillusionment" at all, as shown in this chart:

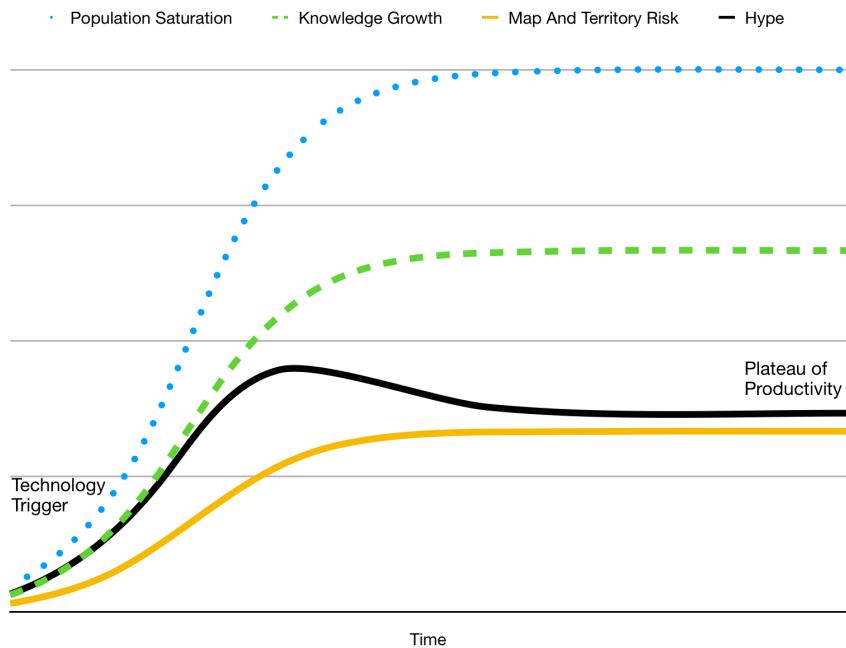

Figure 21.6: Hype Cycle 2: Slower growth of Map and Territory Risk means no "Trough of Disillusionment"

21.4 Evolution

The chapter on Communication Risk introduced the following model for ideas:

But what happens next? As we saw in Boundary Risk, the **Peter Principle** applies, people will use dependencies up to the point when they start breaking down.

⁷

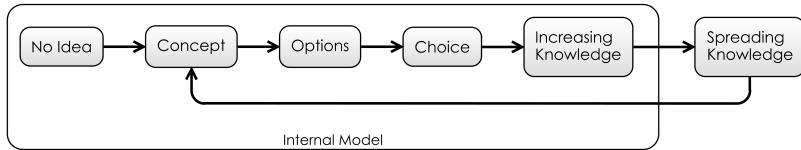

Figure 21.7: Spread of information between Internal Models

Example: Metrics

Let's dive into a specific example now: someone finds a useful new metric that helps in evaluating performance.

It might be:

- **SLOC (Source Lines Of Code):** i.e. the number of lines of code each developer writes per day/week whatever.
- **Function Points:** the number of function points a person on the team completes, each sprint.
- **Code Coverage:** the number of lines of code exercised by unit tests.
- **Response Time:** the time it takes to respond to an emergency call, say, or to go from a feature request to production.
- **Release cadence:** number of releases a team performs, per month, say.

With some skill, they may be able to *correlate* this metric against some other more abstract measure of success. For example:

quality is correlated with more releases

user-satisfaction is correlated with SLOC

revenue is correlated with response time

Because the *thing on the right* is easier to measure than the *thing on the left*, it becomes used as a proxy (or, Map) for the thing they are really interested in (the Territory). At this point, it's *easy* to communicate this idea with the rest of the team, and the *market value of the idea is high*: it is a useful representation of reality, which is shown to be accurate at a particular point in time.

But *correlation* doesn't imply *causation*. The *cause* might be different:

- quality and number of releases might both be down to the simplicity of the product.
- user satisfaction and SLOC might both be down to the calibre of the developers.
- response time and revenue might both be down to clever team planning.

Metrics are seductive because they simplify reality and are easily communicated. But they *inherently* contain Map and Territory Risk: By relying *only* on the metrics, you're not really *seeing* the reality.

The devil is in the detail.

Reality Evolves

In the case of metrics, this is where they start being used for more than just indicators, but as measures of performance or targets:

- If a team is *told* to do lots of releases, they will perform lots of releases *at the expense of something else*.
- If team members are promoted according to SLOC, they will make sure their code takes up as many lines as possible.
- In the UK, ambulances were asked to wait before admitting patients to Emergency wards, in order that hospitals could meet their targets⁸.

Some of this seems obvious: *Of course* SLOC is a terrible measure performance! We're not that stupid anymore. The problem is, it's not so much the *choice* of metric, but the fact that *all* metrics merely approximate reality with a few numbers. The map is *always* simpler than the territory, therefore there can be no perfect metrics.

In the same way that markets evolve to demand more features model doesn't cover it, ideas and products all eventually have their day and decline in usefulness.

Bad Ideas

There are plenty of ideas which *seem a really good idea at the time* but then end up being terrible. It's only as we *learn about the products* and realize the hidden Map and Territory Risk⁹ that we stop using them. While SLOC is a minor offender, CFCs¹⁰ or Leaded Petrol¹¹ are more significant examples.

⁸https://en.wikipedia.org/wiki/NHS_targets

⁹

¹⁰<https://en.wikipedia.org/wiki/Chlorofluorocarbon>

¹¹<https://en.wikipedia.org/wiki/Tetraethyllead>

The following Hyph Cycle chart shows an initially promising idea that turns out to be terrible, and there is a “Period of Inoculation” where the population realise their mistake. There is “negative hype” as they work to phase out the offending idea:

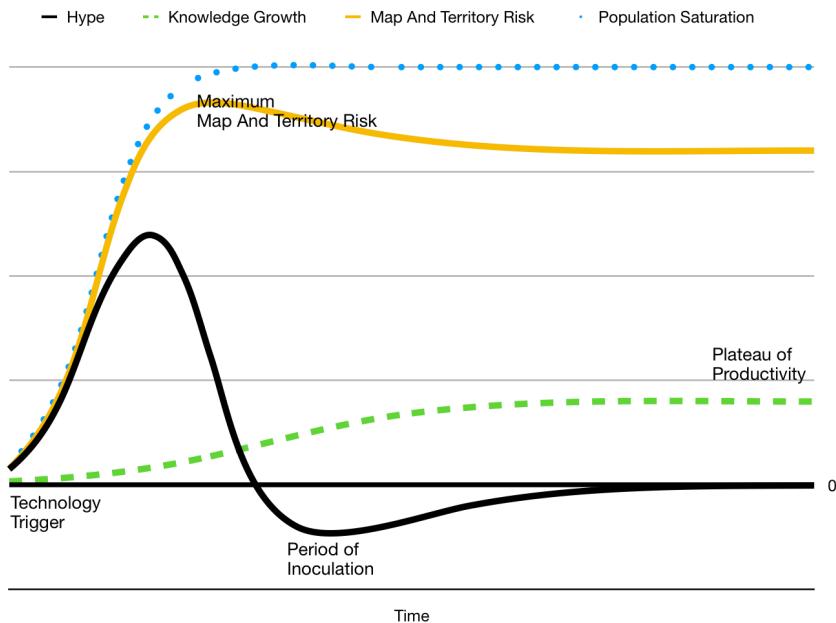

Figure 21.8: Hype Cycle For Something that turns out to be a bad idea

21.5 Humans and Machines

In the example of the SatNav, we saw how the *quality* of Map and Territory Risk, but for software systems it is a production crisis involving 3am calls and backups.

For Humans, Map and Territory Risk¹² is exacerbated by cognitive biases¹³:

“Cognitive biases are systematic patterns of deviation from norm or rationality in judgment, and are often studied in psychology and behavioral economics.”

—Cognitive Bias, Wikipedia¹⁴

¹²

¹³https://en.wikipedia.org/wiki/List_of_cognitive_biases

¹⁴https://en.wikipedia.org/wiki/List_of_cognitive_biases

There are *lots* of cognitive biases. But let's just look at a couple that are relevant to Map and Territory Risk:

- **Availability Heuristic:** People overestimate the importance of knowledge they have been exposed to.
- **The Ostrich Effect:** Which is where dangerous information is ignored or avoided because of the emotions it will evoke.
- **Bandwagon Effect:** People like to believe things that other people believe. Could this be a factor in the existence of the Hype Cycle?

21.6 Hierarchical Organisations

Map And Territory Risk “trickles down” through an organisation. The higher levels have an outsize ability to pervert the incentives at lower levels because once an organisation begins to pursue a “bullshit objective”, the whole company can align to this.

The Huffington Post¹⁵ paints a brilliant picture of how Volkswagen managed to get caught faking their emissions tests. As they point out:

“The leadership culture of VW probably amplified the problem by disconnecting itself from the values and trajectory of society, by entrenching in what another executive in the auto industry once called a “bullshit-castle”... No engineer wakes up in the morning and thinks: OK, today I want to build devices that deceive our customers and destroy our planet. Yet it happened. Why? Because of hubris at the top.”

—Otto Scharmer, *Huffington Post*¹⁶.

This article identifies the following process:

- **De-sensing:** VW Executives ignored *The Territory* society around them (such as the green movement), ensuring their maps were out of date. The top-down culture made it hard for reality to propagate back up the hierarchy.
- **Hubris/Absencing:** They pursued their own metrics of *volume* and *cost*, rather than seeking out others (a la the Availability Heuristic Bias). That is, focusing on their own *Map*, which is *easier* than checking the *Territory*. (See Hubris.)

¹⁵https://www.huffingtonpost.com/otto-scharmer/the-fish-rots-from-the-he_b_8208652.html

¹⁶https://www.huffingtonpost.com/otto-scharmer/the-fish-rots-from-the-he_b_8208652.html

- **Deception:** Backed into a corner, engineers had no choice but to find “creative” ways to meet the metrics.
- **Destruction:** Eventually, the truth comes out, to the detriment of the company, the environment and the shareholders. As the article’s title summarizes “A fish rots from the head down”.

Personal Example

A similar (but less catastrophic) personal story from a bank I worked at, where the objectives end up being mis-aligned *within the company*:

1. My team had been tasked with building automated “smoke tests” of an application. But this was bullshit: We only needed to build these *at all* because the application was so complex. The reason it was so complex was...
2. The application was being designed within a “Framework” constructed by the department. However, the framework was only being used by this one application. Building a “reusable” framework which is only used by a single application is bullshit. But, we had to do this because...
3. The organisational structure was created along a “matrix”, with “business function” on one axis and “functional area” on another. Although we were only building the application for a single business function, it was expected to cater with all the requirements from the an entire “functional area”. This was bullshit too, because...
4. The matrix structure was largely the legacy of a recent merger with another department. As Conway’s Law predicts, our software therefore had to reflect this structure. But this was bullshit because...
5. The matrix structure didn’t represent reality in any useful way. It was designed to pacify the budget committee at the higher level, and try to demonstrate attributes such as *control* and *governance*. But this was bullshit too, because...
6. The budget that was given to our department was really based on how much fear the budget holders currently had of the market regulators. But this was bullshit too, because...
7. At a higher level, the executives had realised that our division wasn’t one of the banks strategic strengths, and was working to close it all down anyway.

When faced with so many mis-aligned objectives, it seemed completely hopeless to concentrate on the task at hand. But then, a colleague was able to nihilistically add one final layer to this onion by saying:

8. “It’s all about chasing money, which is bullshit, because life is bullshit.”

Picking Fights

It feels like there’s no way back from that.

All of life might well be a big Map and Territory illusion. But let’s analyse just a bit:

- At each layer, the objectives changed. But, they impacted on the objectives of the layer below.
- Therefore, it seems like the more layers you have, the less likely it is that your objectives become inconsistent between the lower and higher levels.
- On a new project, it seems like a good idea to model this stuff: does the objective of the work you’re about to undertake “align” with the objectives at a higher level?

Trying to spot Map and Territory Risk in the organisation are fragile and likely to change. However, usually, if you are working in a team, you have limited agency to decide which projects you feel are valuable.

This comes down to a personal decision: do you want to spend time working on projects that you know are going in the bin? Some developers have the attitude that, so long as they get paid, it doesn’t matter. But others are in it for the satisfaction of the work itself, so this ends up being a personal call.

(This theme will be developed further in Staging and Classifying

21.7 Markets

So far, we’ve considered what happens to individuals, teams and organisations when told to optimise around a particular objective. In Coordination Risk is a key part of communication.

The languages we adopt or create are *sets of useful abstractions* that allow us to communicate. But what happens when this goes wrong?

Inadequate Equilibria¹⁷ by Eleizer Yudkowsky, looks at how perverse incentive mechanisms break not just departments, but entire societal systems. He highlights one example involving *academics* and *grantmakers* in academia:

¹⁷<https://equilibriabook.com>

- It's not very apparent which scientists are better than which other scientists.
- One proxy is what they've published (scientific papers) and where they've published (journals).
- Universities want to attract research grants, and the best way to do this is to have the best scientists.
- Because "best" isn't measureable, they use the proxy.
- Therefore, immense power rests in the hands of the journals, since they can control the money-proxy.
- Therefore, journals are able to charge large amounts of money to universities for subscriptions.

"Now consider the system of scientific journals... Some journals are prestigious. So university hiring committees pay the most attention to publications in that journal. So people with the best, most interesting-looking publications try to send them to that journal. So if a university hiring committee paid an equal amount of attention to publications in lower-prestige journals, they'd end up granting tenure to less prestigious people. Thus, the whole system is a stable equilibrium that nobody can unilaterally defy except at cost to themselves."

—Inadequate Equilibria, Eleizer Yudkowsky¹⁸

As the book points out, while everyone *persists* in using an inadequate abstraction, the system is broken. However, Coordination

This is a *small example* from a much larger, closely argued book, and it's worth taking the time to read a couple of the chapters on this interesting topic.

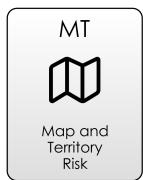

As usual, this chapter forms a grab-bag of examples in a complex topic. But it's time to move on as there is one last stop we have to make on the Risk Landscape.

(NB: The Hype Cycle model is available in **Numbers** form here¹⁹.)

Figure 21.9: Map And Territory Risk

Operational Risk

In this chapter on Operational Risks, we're going to take our head out of the clouds a bit and start considering the realities of running software systems in the real world. After all, Coordination Risk: real-world concerns for anyone running a business.

22.1 A Recap

But before we go there, let's try and recap on where we've come so far. So far, we've been looking at risks to *systems in general* such as:

-
-
-
- Communication Risk: how they mitigate Coordination Risk by taking on Communication Risk.

22.2 Operational Risks

It's tempting to take a very narrow view of the dependencies of a system, but Operational Risks are often caused by dependencies we don't consider - the *context* within which the system is operating. Here are some examples:

- Staff Dependencies (Staff Risk:
 - Freak weather conditions affecting ability of staff to get to work, interrupting the development and support teams.

- Reputational damage caused when staff are rude to the customers.
- Infrastructure Dependencies (Availability Risk):
 - A data-centre going off-line, causing your customers to lose access.
 - A power cut causing backups to fail.
 - Not having enough desks for everyone to sit at.
- Process Dependencies (Process Risk):
 - Regulatory change, which means you have to adapt your business model.
 - Insufficient controls which means you don't notice when some transactions are failing, leaving you out-of-pocket.
 - Data loss because of bugs introduced during an untested release.
- Software Dependencies (Software Dependency Risk):
 - Hackers breaking into the system and bringing your service down.
- Agency Dependencies (Agency Risk):
 - Suppliers deciding to stop supplying you with something you need.
 - Workers going on strike.
 - Employees trying to steal from the company (bad actors).

.. basically, a long laundry-list of everything that can go wrong due to operating in "The Real World".

22.3 Accepting Operational Risk

When processes fail, this is called *Operational Risk*:

tbd - Wikipedia definition

This is a very specific name for Reliability Risk with regard to processes. In the UK each year, X number of people are killed in car accidents. If you regard driving a car from A to B as a process, then you could say that car accidents are Operational Risk. Why do we tolerate such costly operational risk in the UK. Could it be reduced? Well, yes. There are lots of ways. One way is that we could just reduce the speed limit.

It is interesting that we *don't* do that: although we know the driving process fails, and fails in a way that is costly to human lives, as a society we value the freedom, the economic efficiency and time savings that come from not mitigating this operational risk. Changing the speed limit would have it's

own risks, of course: there would be a complicated transition to manage. However, if ten times as many people were killed in car accidents, and it was shown that reducing the speed limit would help, maybe it would be done. The Operational Risk.

The point of this is that we *accept* Operational Risk as we go. However, if opportunities rise to mitigate it, which don't leave us with a net risk increase elsewhere, we'll make those improvements.

22.4 Operational Risk Management

Since we have looked in detail at various types of Dependency Risk:

“Operational Risk Management is the oversight of Operational Risk, including the risk of loss resulting from inadequate or failed internal processes and systems; human factors; or external events.”

—Operational Risk Management, *Wikipedia*¹

So, Operational Risk Management is the purview of dealing with all the types of issues listed above. Sometimes, this will require involvement from developers. For example, as we saw in Development Process, but again reduced the likelihood of bugs making it into production.

Mitigating Operational Risk Increases Complexity

Dependencies are not just things we *use*, then: For a system to run well, it needs to carefully manage unreliable dependencies, and ensure their safety and availability. In the example of the human food system, say, it's the difference between Hunter-Gathering.

22.5 Mitigating Operational Risk

In the real world, Dependencies is somewhat different to that for regular dependencies.

Diagram of Four Ways to Mitigate Complexity Risk

¹https://en.wikipedia.org/wiki/Operational_risk_management

Meeting Reality

(our system: meeting reality, deployment) (event: detection) (sensing / detection) (reaction: monitoring, etc) (pestle, environmental scanning.)

So in this second model, we are now considering that the world is a dangerous, untrustworthy place where *bad things happen*, either deliberately or accidentally. And, since we don't have a perfect understanding of the world, most of the Production Risk.

Putting software into production is Meeting Reality will materialize. If we observe these and take action to mitigate them, then our system can get stronger. cybernetics, antifragile tbd.

It is tempting to delay Meeting Reality. In the past I've seen this stated as:

Pressure to ship becomes greater than pressure to improve tbd

A Risk-First reframing of this might be the balance between:

- The perceived Reputational Risk, Feature Risk
- The perceived Schedule Risks

The "should we ship?" decision is therefore a complex one. In Meeting Reality on our own terms by doing so:

Meet Reality...	Techniques
Sooner	Limited Early-Access Programs, Beta Programs, Soft Launches
More Frequently In Smaller Chunks	[Continuous Delivery], Sprints Modular Releases Trial Populations
With Feedback	User Communities, Support Groups, Monitoring, Logging, Analytics

Anticipation / Preparation

(prediction: how to forecast failures) / anticipation (forecasting) (adaptation: how the system changes in the future) (trend analysis)

Know Thyself

(practicing: e.g. testing failover etc.) (weakness: minimization (see Security risk), penetration testing) (effect: what happens, how much chaos ensues) (changing outside world) (audit)

22.6 Weaknesses

Security of supply

Complex systems (ones which contain multiple, interacting parts, like the ones in the above diagrams) have to contend with their external environments, and try to minimize the ways in which they get interrupted from outside either by *Bad Actors* or external events. In the tbd

Interestingly, security is handled in very similar ways at all sorts of levels:

- **Walls:** defences *around* the complex system, to protect its parts from the external environment.
- **Doors:** ways to get *in* and *out* of the complex system, possibly with *locks*.
- **Guards:** to make sure only the right things go in and out. (i.e. to try and keep out *Bad Actors*).
- **Police:** to defend from *within* the system, against Agency Risk and *invaders*.
- **Subterfuge:** Hiding, camouflage, disguises, pretending to be something else. tbd

These work various levels in our own bodies: our *cells* have *cell walls* around them, and *cell membranes* that act as the guards to allow things in and out. Our *bodies* have *skin* to keep the world out, and we have *mouths, eyes, pores* and so on to allow things in and out. We have an *immune system* to act as the police.

Our societies work in similar ways: in medieval times, a city would have walls, guards and doors to keep out intruders. Nowadays, we have customs control, borders and passports.

We're waking up to the realisation that our software systems need to work the same way: we have Firewalls to protect our organisations, we lock down *ports* on servers to ensure there are the minimum number of doors to guard and we *police* the servers ourselves with monitoring tools and anti-virus software.

These are properties not only of software systems, but biological systems, and businesses too. Let's now take each in turn and inspect it further.

Therefore, one of the best defences against Operational Risk is dealing with the issues quickly once they happen. This requires:

Good Feedback Loops and rapid response to issues.

tbd, talk with John about this

22.7 Meeting Reality

22.8 External Events

We're familiar with the concept of taking steps on the Risk Landscape, wherein we take action are more acceptable to us. However, now we have to contend with the idea that external events *also* change the risk landscape too. If there is sudden bad weather, we might have a risk of a power-cut, and the losses that might entail to productivity or sales. If there is a change of government, that might impact the contracts we've written, or the security of our servers or staff.

Being *in production* is accepting that the Risk Landscape is a volatile, uncaring place. But it's worse than that, since we also have to contend with [Bad Actors], who are deliberately out to exploit weaknesses in the systems we build.

Ordinarily, when we transact with a [Dependency], it should be the case that after the transaction, there is value on both sides of the transaction. This

could be, *you do my accounting*, I pay you money. On both sides, financial risks are reduced. If the price is too high, or too low, we see one or other side getting the better deal, and *capturing an unfair share of the value*.

With a [Bad Actor], we're in a situation more like a zero-sum game: value is *taken* from one party and *transferred* to the other. These are exactly the dependency relationships that societies *don't condone*: there is net zero or *negative* value in the transaction.

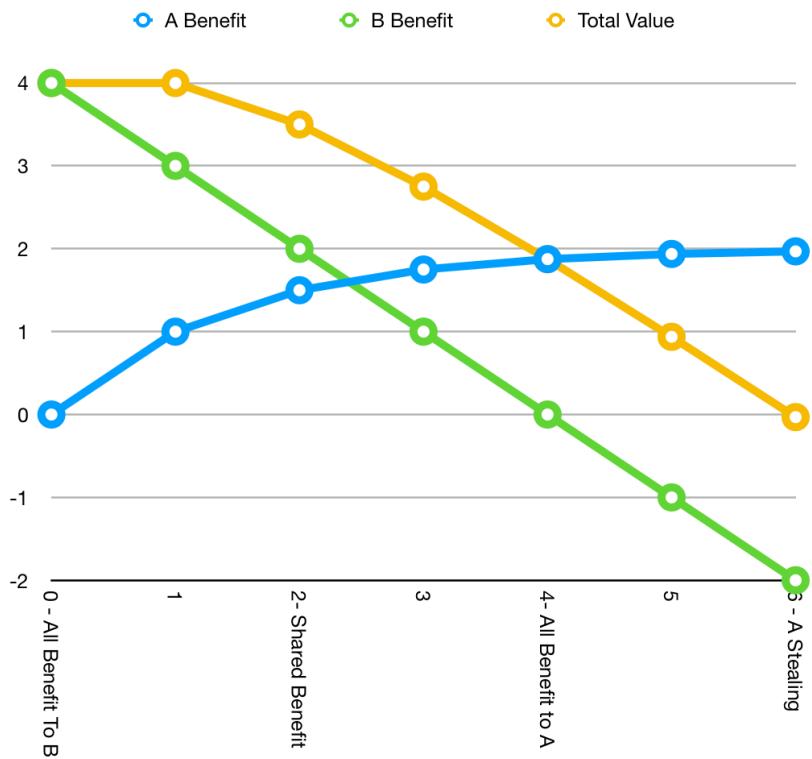

Figure 22.1: In this diagram, B does a deal with A, the value of the product B gets from A is always 4, but the price varies with the X axis. When the price is zero, B captures all the value, but as the price increases, it becomes a worse and worse deal for B, and the net value heads towards zero or negative.

Mitigating Security Risk is a trade-off. You can spent *a lot* of time and effort on this, only to never face the secrets: how to mitigate this

22.9 Effect / Impact

Sometimes, it's possible to measure the impact of Operational Risks. For example, if a software system fails, and leaves customers unable to access it, this can have a measurable financial impact in lost revenues or damages. Car recall example tbd. - fight club

Impact is usually proportional to some of the below variables:

- Number of customers affected.
- Number of transactions affected.
- Size of the transactions
- Length of time systems were affected.

stuff that can go wrong in production

changing stuff in production is harder than changing it in test, as you have to *migrate*.

all the costs of breaking stuff, and damaging the running of the business.

reputation damage (you only get one chance to make a first impression)

- You don't know all the ways the software will get used in production.
- Different browsers, versions of code, accessibility.
- Can you support all the users? Is there enough kit? Will you know?

Correlation - Upgrades (tell story of Research upgrade that went wrong because we were upgrading at the same time as an outage) - Single points of failure.

22.11 Reliability Risk

- Feedback Loops
 - Bug reports, feedback
 - Quality of feedback
 - Internal Controls
 - Agency Risk meets Production Risk (bad actors, controls)

- Contingency Planning
- Disaster Recovery
 - Performance Degradation / Runaway processes (Performance Risk)
 - Support (trade off - promptness vs ability)

Sometimes, the reaction of the company makes things worse - streisand effect

- Poor monitoring, visibility risk meets operational risk (otherwise, it does not make sense)
- Correlation (need a good example here)
- Monitoring Tools and Logs

22.12 Prevention

- How we learn from our mistakes
- You can't know everything
- Reality changes anyway

Staging And Classifying

Our tour is complete.

We've collected on this journey around the Risk Landscape our collection on some solid [Mounting Boards], and do some work in classifying what we've seen.

If you've been reading closely, you'll notice that a number of themes come up again and again within the different chapters. For example, concepts like **Fit, Abstraction, Evolution**. Although we've been looking at patterns of risk across software projects, it's time to look at the *patterns within the patterns*.

23.1 First, A Recap

tbd. list of risks, broken down

23.2 Some Observations

1. The Power Of Abstractions

Abstraction.

There's a good reason for this repetition. Abstraction is at the heart of *everything we do within software*. So, let's now *generalize* what is happening with abstraction, but have in mind *a really simple example*: giving a name to something.

Inventing an Abstraction means:

- **Creating a Feature in the sense that other people can choose to use them, if they fit their requirements.
- **Creating a Boundary. *Boundary Risk is created by abstractions.*
- **Creating a Protocol: what if the person we are communicating with _doesn't know this word?
- **Increasing Complexity.** Because, the more words we have, the more complex the language is.

tbd, diagram.

Choosing an Abstraction means:

- **Overcoming a Learning Curve.
- **Accepting Boundary Risks.
- **Accepting Map And Territory Risk.** Because the word refers to the *concept* of the thing, and *not the thing itself*.

tbd. diagram

Depending On an Abstraction means:

- **Living with Dependency Risk:** We depend on a word in our language, or a function in our library, or a service on the internet. But all of these things are *unreliable*. The word might not communicate what you want it to, or be understood by the audience, the function might not work, the service might be down.
- **Accepting Evolution.
- **Accepting Coordination Risk, we need to consider how to work with it.

tbd diagram.

2. Your Feature Risk is Someone Else's Dependency Risk

In the Feature Risk went further, looking at specific aspects of being the supplier of an IT service as a dependency.

However, over the rest of the Dependency Risk chapters, we looked at this from the point of view of *being a client to someone else*: you want to find trustworthy, reliable dependencies that don't give up when you least want them to.

So Feature Risk when you're the supplier.

We've looked at three dimensions of Feature Risk: - Fit - Evolution - Audience
(recap this)

Dependency Risk has three dimensions too:

- Schedule (things happening in time, running out of stuff. e.g I need enough money to get this done, etc. I need enough patience, enough loyalty, trust, entente.)
- Technology (depending on software, hardware, etc.)
- Organisation (arrangements of people)
- Agency (people/machines/processes/organisations doing what you asked, working with you)
-

Using a dependency requires learning a *protocol*. You have to learn to use it. Maybe it learns you. This requires changes to your internal model.

Internal Model - Communication – Dependency Goal

3. Coordination Risk As Eden

- similar to _threading/deadlocking issues
- Coordination is how you deal with abstractions. and this means communication.

tbd diagram: abstractions -> agency -> coordination -> communication

One thing that should be apparent is that there are similarities in the risks between all the kinds of

- draw a diagram of this system. mark on all the different risks using numbers. mention specifically that since this is a diagram, it is a "map".

23.4 Patterns

As we said at the start our work, we need to be able to explain what the risks are, and what we expect to do about them.

So, lastly in part 2 let's put our language to work, and look at some past project failures. Can we apply our lexicon to them?

On to Stories Of Failure.

Stories Of Failure

2. Failure Modes

- Understanding Failure: what exactly does it mean to fail?
- Personal Failures
 - CapsLock: complexity, not using tools.
 - Configuration Tool (Complexity, feature fit, bugs in hibernate (dependency risk, then dead-end risk), difficulty mapping domain model)
 - Wide Learning (Funding, but also complexity), did we know what we were building? Agency risk
 - AreAye - needless complexity XMLBox
 - Agora: Notes / Typing. (Complexity Risk) Archipelago
 - PDC: website redesign. funding. i.e. schedule risk
 - Hawk: complexity risk in the software. but actually, they made it work. offshoring.
 - Dark: market/feature fit?
 - J10: marketing / market fit / Complexity in spades. algorithmic complexity
 - DSL: complexity (code generation). complexity = layers. team dynamics.
 - REF: complexity. agency risk. failure of goals. m&t.
 - REF Testing: complexity risk. communication risk?
 - HSC: Trader Comments: feature fit.
 - HSC: Takeover of Symph: Complexity (of change)
 - TT: Feature Fit
- Boehm.

JC Example 1: Compensation Workbench, rules to uplift payrolls annually based on certain definitions. e.g tied into performance grading, min wage. Was done off s/s, out of HR system. Analysis done on S/s. But wanted to do it in the HR database. It took a lot longer than it should. Underestimated the complexity. Excel could be infinitely complex, but if you standardize, you lose that. The customer hadn't got experience of big IT projects - scope creep. No real sense of prioritisation and focusing on what was important. PM was nice, but didn't understand delivery management. (i.e. managing risks and issues). Had short timescale, lead delivery resource underestimated. 2m exercise. Lasted 5m in the end, but not with full functionality.

Application

Coming Next

- preview of what's to come in part 3.

Bad to leave on the failure notes, let's talk about some successes.

3. What's To Come

- risk based debugging.
- risk based coding.

Estimates

1. Purpose of Estimating
2. (coordination risk)
3. trying to work out *the value* of doing some work
4. How Estimates Fail
5. Hidden Risk
6. Visible Risk
- 7.

26.1 How Estimates Fail

The problem with a developer answering a question such as:

How long will it take to deliver X

Is the following:

- The developer likely doesn't know what X is, and any description of it is inadequate anyway (Invisibility Risk).
- The developer has a less-than-complete understanding of the environment he will be delivering X in (Complexity Risk).
- The developer has some vague ideas about how to do X, but he'll need to try out various approaches until he finds exactly the right one (Boundary Risk).

- The developer has no idea what Hidden Risk will surface when he starts work on it.
- What will happen if he takes too long and misses the date by a day / week / - month / year. (Schedule Risk)

... and so on. So, his estimate is both wrong, and contingent on what exact risks appear.

26.2 An Aside

tbd quality, time, functionality pick two of three.

26.3 Agile

One alternative approach, must espoused in DevOps / Agile is to pick a short-enough period of time (say, two days or two weeks), and figure out what the most meaningful step towards achieving an objective would be in that time. By fixing the time period, we remove Schedule Risk from the equation.

The problems with this are: - First, this is just Gradient Descent. - Second, what happens after the two days? If you *abandon the work*, then maybe you are giving up too early: a day or two more might have cracked it. If you undergo the planning process again, you might decide that another objective is more important. Constantly switching ideas all the time *might not get you anywhere*. - Third, how to choose the time period? In Scrum it's between tbd. But, lots of people are saying go smaller.

The choice of using gradient descent means that you have given up on [Grand Objectives].

But essentially, we have here the difference between "Walking towards a destination" and "Walking downhill".

Or, a planned economy and a market economy. But, we don't live in *either*: everyone lives in some mixture of the two.

So, is there a synthesis of these two approaches that makes sense?

Devops approach.
